

1A Standalone Linear Li - Ion Battery Charger

General Description

The HX4056 is a complete constant-current/constant-voltage linear charger for single cell lithium-ion batteries. Its ESOP8 package and low external component count make the HX4056 ideally suited for portable applications. Furthermore, the HX4056 is specifically designed to work within USB power specifications. No external sense resistor is needed, and no blocking diode is required due to the internal MOSFET architecture. Thermal feedback regulates the charge current to limit the die temperature during high power operation or high ambient temperature. The charge voltage is fixed at 4.2V, and the charge current can be programmed externally with a single resistor. The HX4056 automatically terminates the charge cycle when the charge current drops to 1/10th the programmed value after the final float voltage is reached. When the input supply (wall adapter or USB supply) is removed, the HX4056 automatically enters a low current state, dropping the battery drain current to less than 1µA. Other features include charge current monitor, automatic recharge and a status pin to indicate charge termination and the presence of an input voltage.

Order Information

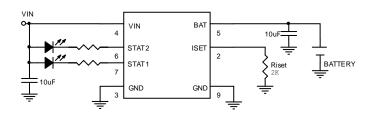

Applications

- ♦ Portable Media Players/MP3 players
- Cellular and Smart mobile phone
- ♦ PDA/DSC
- ♦ Bluetooth Applications

Features

- Programmable Charge Current up to 1A
- No MOSFET, Sense Resistor or Blocking Diode Required
- Constant-Current/Constant-Voltage Operation with Thermal Regulation to Maximize
- Charge Rate Without Risk of Overheating
- ◆ 4.2V Charge Voltage with ± 1% Accuracy
- Charge Current Monitor Output for Gas Gauging
- Automatic Recharge
- ◆ 2.9V Trickle Charge Threshold
- ◆ C/10 Charge Termination
- Output OCP
- Charging OTP
- Package in ESOP8

Typical Application Circuit

Functional Pin Description

| Package Type | Pin Configurations | | |
|--------------|--------------------|--|--|
| ESOP8 | NC 1 | | |

| Pin | Name | Description | |
|-----|-------|---|--|
| 1、8 | NC | No Connector. | |
| | | Charge Current Program and Charge Current Monitor Pin. The charge current is | |
| 2 | ISET | programmed by connecting a 1% resistor, R _{ISET} , to ground. When charging in | |
| 2 | | constant-current mode, this pin servos to 1V. In all modes, the voltage on this pin can be | |
| | | used to measure the charge current using the following formula: IBAT=1000/RISET | |
| 3、9 | GND | Ground. | |
| 4 | VIN | Positive Input Supply Voltage. | |
| 5 | BAT | Charge Current Output. Provides charge current to the battery and regulates the final float | |
| 3 | DAT | voltage to 4.2V. An internal precision resistor divider from this pin sets the float voltage. | |
| | | Open-Drain Charge Status Output. When the battery is charging, the STAT2 pin could be | |
| 6 | STAT2 | pulled High by an external pull high resistor. When the charge cycle is completed, the pin is | |
| | | pulled Low by an internal N-channel MOSFET. | |
| | STAT1 | Open-Drain Charge Status Output. When the battery is charging, the STAT1 pin is pulled | |
| 7 | | low by an internal N-channel MOSFET. When the charge cycle is completed, the pin could | |
| | | be pulled High by an external pull high resistor. | |

Applications Information

The HX4056 is a single cell lithium-ion battery charger using a constant-current/constant-voltage algorithm. It can deliver up to 1A of charge current with a final float voltage accuracy of $\pm 1\%$ (using a good thermal PCB layout).

The HX 4056 includes an internal P-channel power MOSFET and thermal regulation circuitry. No blocking diode or external current sense resistor is required; thus, the basic charger circuit requires only three external components. Furthermore, the HX4056 is capable of operating from a USB power source.

Normal Charge Cycle

A charge cycle begins when the voltage at the VIN pin rises above the UVLO threshold level and a 1% program resistor is connected from the ISET pin to ground or when a battery is connected to the charger output. If the BAT pin is less than 2.9V, the charger enters trickle charge mode.

When the BAT pin voltage rises above 2.9V, the charger enters constant-current mode, where the programmed charge current is supplied to the battery. When the BAT pin approaches the final float voltage (4.2V), the HX4056 enters constant-voltage mode and the charge current begins to decrease. When the charge current drops to 1/10 of the programmed value the charge cycle ends.

Programming Charge Current

The charge current is programmed using a single resistor from the ISET pin to ground. The battery charge current is 1000 times the current out of the ISET pin. The program resistor and the charge current are calculated using the following equations:

R_{ISET}=1000÷I_{BAT},

I_{BAT}=1000÷R_{ISET}

The charge current out of the BAT pin can be determined at any time by monitoring the ISET pin voltage using the following equation:

 $I_{BAT}=V_{ISET} \div R_{ISET} \times 1000$

Charge Status Indicator (STAT1,STAT2)

The charge status output has two different states: strong pull-down (~5mA) and high impedance. The strong pull-down state indicates that the HX4056 is in a charge cycle. High impedance indicates that the charge cycle complete or the HX4056 is in under voltage lockout mode: either VIN is less than 100mV above the BAT pin voltage or insufficient voltage is applied to the VIN pin. A microprocessor can be used to distinguish between these two states.

| Charge Stage | STAT1 Status | STAT2 Status |
|-----------------|--------------|--------------|
| Charging | Low | High |
| Charge Complete | High | Low |

Charge Termination

A charge cycle is terminated when the charge current falls to 1/10 the ISET rammed value after the final float voltage is reached. This condition is detected by using an internal, filtered comparator to monitor the ISET pin. When the ISET pin voltage falls below $100\,\text{mV}$ for longer than t_{TERM} (typically 1ms), charging is terminated. The charge current is latched off and the LP4056 enters standby mode, where the input supply current drops to $200\,\mu\text{A}$. In this state, all loads on the BAT pin must be supplied by the battery. (Note: C/10 termination is disabled in trickle charging and thermal limiting modes).

V1.3 Page 5 of 7

Thermal Limit

An internal thermal feedback loop reduces the programmed charge current if the die temperature attempts to rise above a preset value of approximately 125°C. This feature protects the HX4056 from excessive temperature and allows the user to push the limits of the power handling capability of a given circuit board without risk of damaging the HX4056. The charge current can be set according to typical (not worst-case) ambient temperature with the assurance that the charger will automatically reduce the current in worst-case conditions.

Automatic Recharge

The HX4056 constantly monitors the BAT pin voltage in standby mode. If this voltage drops below the 4.05V recharge threshold (V_{RECHRG}), another charge cycle begins and current is once again supplied to the battery. To manually restart a charge cycle when in standby mode, the input voltage must be removed and reapplied.

Power Dissipation

The conditions that cause the HX4056 to reduce charge current through thermal feedback can be approximated by considering the power dissipated in the IC. Nearly all of this power dissipation is generated by the internal MOSFET—this is calculated to be approximately:

$$PD=(V_{IN} - V_{BAT}) \times I_{BAT}$$

Where PD is the power dissipated, V_{IN} is the input supply voltage, V_{BAT} is the battery voltage and I_{BAT} is the charge current. The approximate ambient temperature at which the thermal feedback begins to protect the IC is:

$$T_A=125$$
°C-($V_{IN}-V_{BAT}$)× I_{BAT} × θ_{JA}

VIN Bypass Capacitor

Many types of capacitors can be used for input bypassing; however, caution must be exercised when using multilayer ceramic capacitors. Because of the self-resonant and high Q characteristics of some types of ceramic capacitors, high voltage transients can be generated under some start-up conditions, such as connecting the charger input to a live power source. Adding a 1.5Ω resistor in series with an X5R ceramic capacitor will minimize start-up voltage transients.

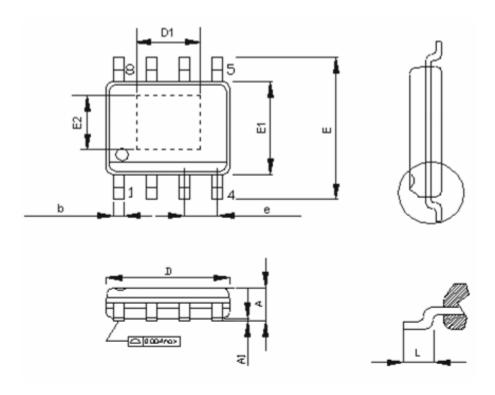

Layout Considerations

- For the main current paths as indicated in bold lines, keep their traces short and wide.
- Put the input capacitor as dose as possible to the device pins (VIN and GND).
- Connect all analog grounds to a command node and then connect the command node to the power ground behind the output capacitors.
