## Dual Stepper Motor Driver with Ultra-small Micro Steps

The LV8714 is a fully integrated dual bipolar/unipolar stepper motor driver with ultra-small micro step drive capability. Alternatively, it can be used to drive four DC motors independently. The device includes low  $R_{DS(ON)}$  (upper + lower =  $0.9\Omega$ ) type MOSFETs based quad H-bridges with gate drivers and can drive up to 1.5A per H-bridge. Synchronous rectification control is implemented for all H-bridges to lower power dissipation during a MOSFET switching. The device implements constant-current control using PWM at 125 kHz (typ.) switching frequency that enables the least noise motor drive solution. A built-in linear regulator powers internal logic circuit directly from the motor supply voltage,  $V_M$ , thus eliminating need for any external regulator.

A proprietary internal current sensing mechanism is implemented that eliminates up to four external current sense power resistors and improves the system energy efficiency significantly. External  $V_{REF}$  input signal for each H-bridge controls the drive step size and can achieve over 256 micro step resolution. Individual controls signals (ENAx and INx) are provided for controlling each H-bridge channel independently with forward and reverse direction control. To enhance energy efficiency further, the device can be put into a power saving standby mode, when idle.

### Features

- Integrated quad H-bridges with independent controls
  - Dual bipolar/unipolar stepper motor or quad DC motor drive
  - Forward and reverse direction control
- Low  $R_{DS(ON)}$  (upper + lower =  $0.9\Omega$ ) type MOSFETs
- Proprietary internal current sensing
  - Eliminates up to four external current sense power resistors
- Over 256 micro step resolution with external  $V_{REF}$  inputs
- Single supply operation with a built-in internal regulator
- No external component for driving internal MOSFETs
- Constant-current control with 125 kHz (typ.) PWM switching frequency
- Low power standby mode when idle
- Synchronous rectification to reduce power dissipation
- In-built system protection features such as:
  - Under-voltage
  - Over-current
  - Over-temperature

### Typical Applications

- Surveillance Camera
- Stage light
- Scanner
- Printer

## MAXIMUM RATINGS (Note 1)

Parameter	Symbol	Value	Unit
Motor Supply Voltage (Note 2)	$V_M$	18	V
Logic Input Voltage (Note 3)	$V_{IN}$	6	V
Output Peak Current per channel (Note 4)	$I_{O(peak)}$	1.75	A
Output current per channel	$I_{O(max)}$	1.5	A
Allowable Power Dissipation (Note 5)	$P_d$	4.86	W
Storage Temperature	$T_{stg}$	-55 to 150	°C
Junction Temperature	$T_J$	150	°C
Moisture Sensitivity Level (MSL) (Note 6)	MSL	3	-
Lead Temperature Soldering Pb-Free Versions (10sec or less) (Note 7)	$T_{SLD}$	260	°C

1. Stresses exceeding those listed in the Absolute Maximum Rating table may damage the device. If any of these limits are exceeded, device functionality should not be assumed, damage may occur and reliability may be affected.
2. Motor power supply pins are VM1, VM2, VM3 and VM4.
3. Logic input pins are PS, ENA1, IN1, ENA2, IN2, ENA3, IN3, ENA4 and IN4.
4. Condition for measuring the output peak current is that total time duration  $\leq 10$  ms (PWM duty cycle = 20%) at each channel.
5. Specified circuit board : 90mm $\times$  90mm $\times$  1.6mm, glass epoxy 4-layer board, with backside mounting. It has 1 oz internal power and ground planes and 1/2 oz copper traces on top and bottom of the board. Please refer to Thermal Test Conditions of page 23.
6. Moisture Sensitivity Level (MSL): 3 per IPC/JEDEC standard: J-STD-020A
7. For information, please refer to our Soldering and Mounting Techniques Reference Manual, SOLDERRM/D <http://www.onsemi.com/pub/link/Collateral/SOLDERRM-D.PDF>

## THERMAL CHARACTERISTICS

Parameter	Symbol	Value	Unit
Thermal Resistance, Junction-to-Ambient (Note 5)	$R_{\theta JA}$	25.7	°C/W
Thermal Resistance, Junction-to-Case (Top) (Note 5)	$R_{\psi JT}$	6	°C/W

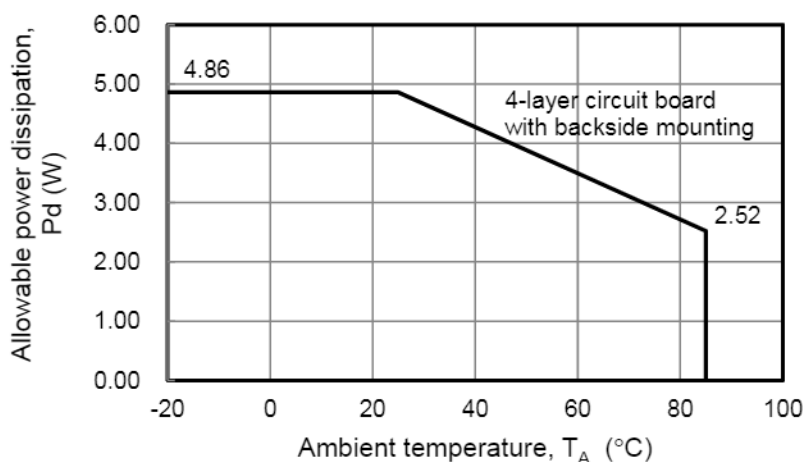

Figure 6. Power Dissipation vs Ambient Temperature Characteristic

9. Product parametric performance is indicated in the Electrical Characteristics for the listed test conditions, unless otherwise noted. Product performance may not be indicated by the Electrical Characteristics if operated under different conditions.

TYPICAL CHARACTERISTICS

TYPICAL CHARACTERISTICS

TYPICAL CHARACTERISTICS

**FUNCTIONAL DESCRIPTION**

**Power Supply Pins (VM1, VM2, VM3 AND VM4)**

The LV8714 has four power supply pins, VM1, VM2, VM3, and VM4, connected internally. Hence, it is must that all power supply pins are connected to the same power supply rail externally. VM1 also supplies power to internal circuits through an internal voltage regulator.

It is highly recommended to provide a decoupling capacitor of 47µF close to the VM1 pin.

**Internal 3.3V Voltage Regulator Pin (VREG3)**

An internal 3.3V voltage regulator acts a power source for internal logic, oscillator, and protection circuits. Output of this regulator is connected to the VREG3 pin. Do not use the VREG3 pin to drive any external load. It is recommended to connect a 0.1µF decoupling capacitor to the VREG3 pin.

**Internal Regulator (VM-3.3V)**

An VM-3.3V regulator is integrated in the LV8714. This regulator provides required biasing for upper MOSFETs of each channel.

**Power Save Mode Selection Pin (PS)**

When the LV8714 is idle, to save power, it can be put to a power saving, Standby mode by applying logic low to the PS pin. While in the Standby mode, all internal circuits of the LV8714 including voltage regulators are put into inactive state. Table 1 shows mode selection of the LV8714 using the PS pin

Logic Input at PS Pin	Mode	Internal Circuits
Low or Open	Standby	Inactive
High	Operating	Active

**Table 1: LV8714 mode selection using the PS pin**

Figure 23 shows an equivalent internal circuit of the PS pin input.

**Figure 23. Equivalent circuit of the PS pin**

**Channel Control Pins (ENAx, INx)**

Each channel of the LV8714 is controlled independently by corresponding ENAx and INx pins. Figure 24 shows an equivalent internal circuit of these input pins.

**Figure 24. Equivalent circuit of ENAx, INx**

**Motor Drive Output Pins (OUTxx)**

The LV8714 has quad built-in H-bridges for driving stepper or DC motors. Each H-bridge (channel) is made up of upper side P-MOSFETs and lower side N-MOSFETs. Output of each channel is connected to OUTxA or OUTxB pins. When a channel is configured to drive a stepper motor in forward direction, OUTxA becomes high output and in reverse direction, OUTxB becomes high output.

**Reference Voltage Input Pins (VREFx)**

Step size of a stepper motor drive is controlled by providing a reference voltage signal at VREFx pin for each channel. Resolution of the VREFx input enables ultra-small micro step drive of a stepper motor in combination with the INx input. The coil current is proportional to the analog voltage amplitude at the VREFx pin.

Figure 25 shows an equivalent circuit of VREFx input pins.

**Figure 25. Equivalent circuit of VREF1-4**

**Current Sense Resistor Pins (RCSx)**

The LV8714 implements a proprietary current sense mechanism for each channel and doesn't require any external current sense power resistor, thus providing

loss-less current control that improves the energy efficiency of the system.

To control a coil current, the individual RCSx pin is provided for each channel. A resistor connected at this RCSx pin decides the coil current. The coil current is sensed internally and fed back to RCS pin with the ratio of 1/4000. And, the output duty cycle adjusted such that the RCSx voltage level is equal to 1/3 of the VREFx pin voltage. Figure 26 shows the equivalent circuit of current control.

Figure 26. Equivalent circuit of current control

Equation 1 is utilized to calculate the coil current,  $I_{OUT}$ .

$$\frac{I_{OUT}}{4000} \cdot R_{CS} = \frac{V_{REF}}{3} \dots \dots \dots (1)$$

Where,

- $I_{OUT}$  = Coil current [A]
- $R_{CS}$  = Resistance between RCSx and GND [ $\Omega$ ]
- $V_{REF}$  = Input voltage at the VREFx pin [V]

For example, in case of

$$R_{CS} = 1k\Omega$$

$$V_{REF} = 0.6V$$

The coil current is

$$I_{OUT} = \frac{4000 \times 0.6}{3 \times 1000} = 0.8A$$

# LV8714TA

## DETAILED DESCRIPTION

### Stepper Motor Direction Control

The stepper motor rotation direction is determined by phase lead/lag relation between INx inputs of the LV8714 as shown in Table 2 and Table 3.

INx	ENA1, ENA2	Phase				Direction
		0-90	90-180	180-270	270-360	
IN1	H	L	L	H	H	Forward
IN2	H	H	L	L	H	
IN1	H	H	L	L	H	Reverse
IN2	H	L	L	H	H	

**Table 2: Stepper Motor Direction control by IN1 and IN2**

INx	ENA3, ENA4	Phase				Direction
		0-90	90-180	180-270	270-360	
IN3	H	L	L	H	H	Forward
IN4	H	H	L	L	H	
IN3	H	H	L	L	H	Reverse
IN4	H	L	L	H	H	

**Table 3: Stepper Motor Direction control by IN3 and IN4**

### DC Motor Direction Control

The LV8714 utilizes ENAx and INx to control the DC motor rotation direction as shown in Table 4.

Input signal		Output		Direction
ENAx	INx	OUTxA	OUTxB	
L	-	Off	Off	
H	L	High	Low	Forward
H	H	Low	High	Reverse

X represents a channel number

**Table 4: DC Motor Direction Control by ENAx and INx**

### Stepper Motor Coil Current Control

Stepper motor coil current is controlled in proportional to VREFx and RCSx as shown in equation 1 previously. Two phase outputs (A and B) for each stepper motor are controlled by combination of INx and VREFx inputs as shown in Table 5.

Input			Output (coil current)	
INx	VREFx	ENAx	Amplitude	Polarity
Low	Analog	High	Proportional to VREFx	A to B
High	Analog	High	Proportional to VREFx	B to A

**Table 5: Stepper Motor Coil Current Control**

Figure 27 and 28 show example waveforms of output current with in response to VREFx, ENAx and INx input.

**Figure 27. Example waveforms for full step (forward) control**

Figure 28. Example waveforms for 1/256 step (forward) control

**PWM Constant-Current Control**

The LV8714 implements constant-current control drive by applying PWM switching to the output pin.

When the coil current becomes equal to the set target value (as determined by equation 1), the constant current control mechanism gets activated and performs a repetitive sequence of Charge → Slow Decay → Fast Decay (fixed 2μs) → Charge... as shown in Figure 29. The period for each sequence is fixed at 8μs(typ.).

Figure 29 shows timing chart of PWM based constant-current control.

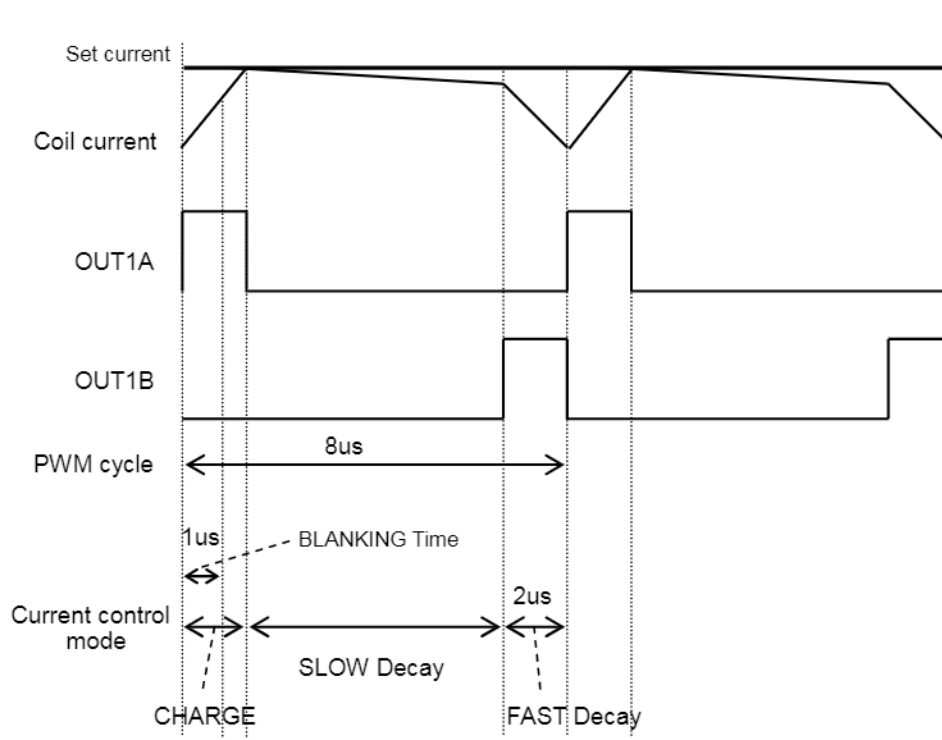

Figure 29. Timing chart of PWM based constant-current

**Three Modes of Constant-Current Control**

Each PWM cycle of constant-current control is made up of three distinct intervals – Charge, Slow Decay and Fast Decay.

Example: Current direction A to B

**Charge:**  
Voltage is applied to the coil until the coil current becomes equal to the target (A = High, B = Low).

**Slow Decay:**  
Output A and B are shorted internally resulting in circular current (A = Low, B = Low).

**Fast Decay:**  
Inverted bias is applied to discharge the coil current (A = Low, B = High) that results in decreases of the coil current.

These intervals (Charge, Slow Decay and Fast Decay) are results of MOSFET switching as shown in Figure 30.

Figure 30. MOSFET switching sequence for constant-current control

Whenever, there is a switch from the upper MOSFET to the lower MOSFET of the same leg, the fixed dead time of  $0.375\mu\text{s}$  is provided to avoid turning on both MOSFETs on at the same time. During this time, the coil current flows through the body diode of the MOSFET as seen in (2), (4) and (6) events in figure 30.

Table 6 and Table 7 show status of MOSFETs during various intervals in a PWM cycle for different current polarities.

OUTxA→OUTxB

Output Tr	CHARGE	SLOW Decay	FAST Decay
U1	ON	OFF	OFF
U2	OFF	OFF	ON
L1	OFF	ON	ON
L2	ON	ON	OFF

Table 6: MOSFET Switching Sequence for OUTxA→OUTxB polarity

OUTxB→OUTxA

Output Tr	CHARGE	SLOW Decay	FAST Decay

U2	ON	OFF	OFF
L1	ON	ON	OFF
L2	OFF	ON	ON

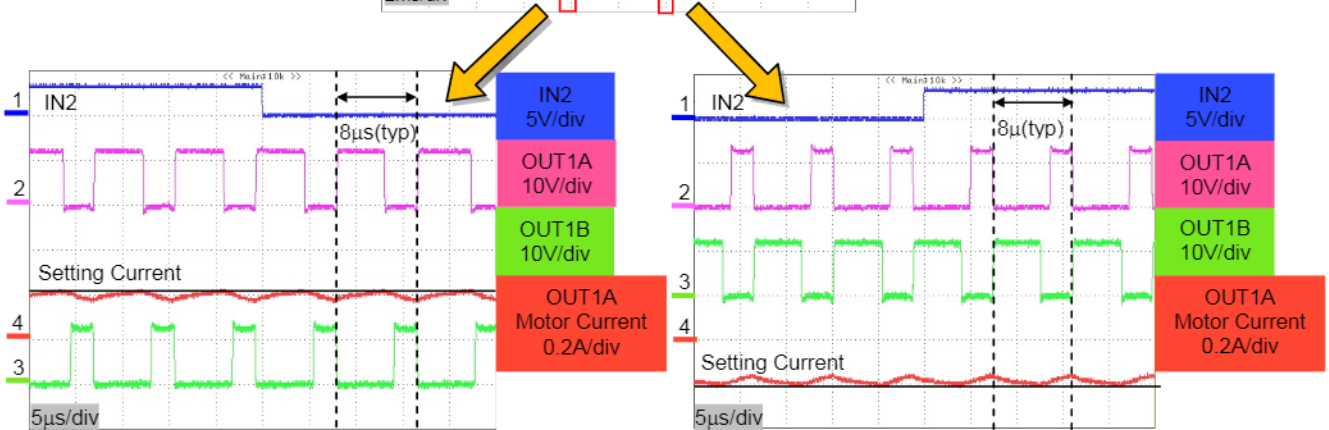

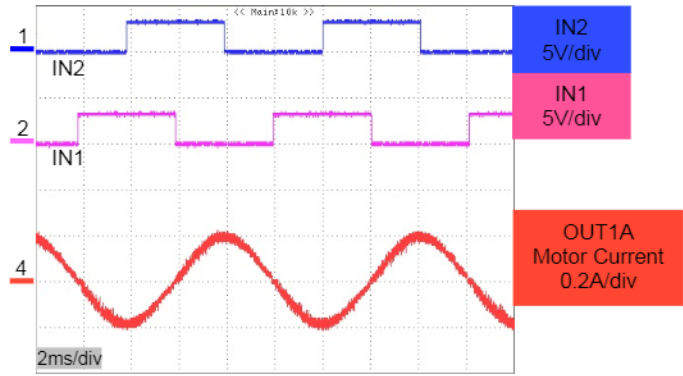

Table 7: MOSFET Switching Sequence for OUTxB→OUTxA polarity

Figure 31 shows example waveforms of the stepper motor with 1/16 step and constant-current control.

Figure 32 shows example waveforms of three events – Charge, Slow Decay and Fast Decay.

# LV8714TA

**1/16 step**  
 VM=12V  
 VREF1/2=0.23V  
 (Iout≈0.2A)  
 RCS1/2=1.5kΩ  
 IN1=IN2≈ 125Hz  
 Rcoil=15Ω

Constant current control is synchronized to the internal PWM period 8µs (typ).

Figure 31. PWM based constant-current control waveforms of the stepper motor with 1/16 step

VM=12V  
 VREF1/2=0.11V  
 (Iout≈0.1A)  
 RCS1/2=1.5kΩ  
 IN1=IN2=100Hz  
 Rcoil=15Ω

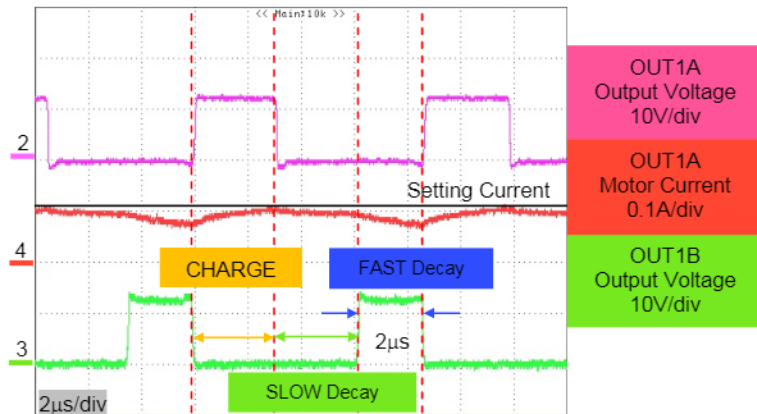

Figure 32. One full PWM cycle of the constant-current control

**Blanking Time**

As the LV8714 switches from Fast Decay to Charge, switching noise can lead to wrong reading by the comparator that is comparing the coil current against the target current. To filter out this switching noise, a fixed 1μs blanking time is provided at the beginning of the Charge interval.

During this blanking time, the comparator ignores the coil current reading and thus avoid false switching to the Slow Decay interval, if the comparator detects the coil current higher than the target current.

**Power-on Reset (POR) Sequence**

At startup, when  $VM1 \geq 4V$  and  $PS = High$ , it takes 50μs for the internal 3.3V regulator to provide stable output. After the 3.3V regulator is in the active state, ENAx needs to be pulled high to enable respective channel output. It is recommended that VREFx input is never floating and the required input signal is applied at least 10μs before ENAx is pulled high. Figure 33 shows POR and fault handling sequence.

POR and Fault Handling Operation Flow

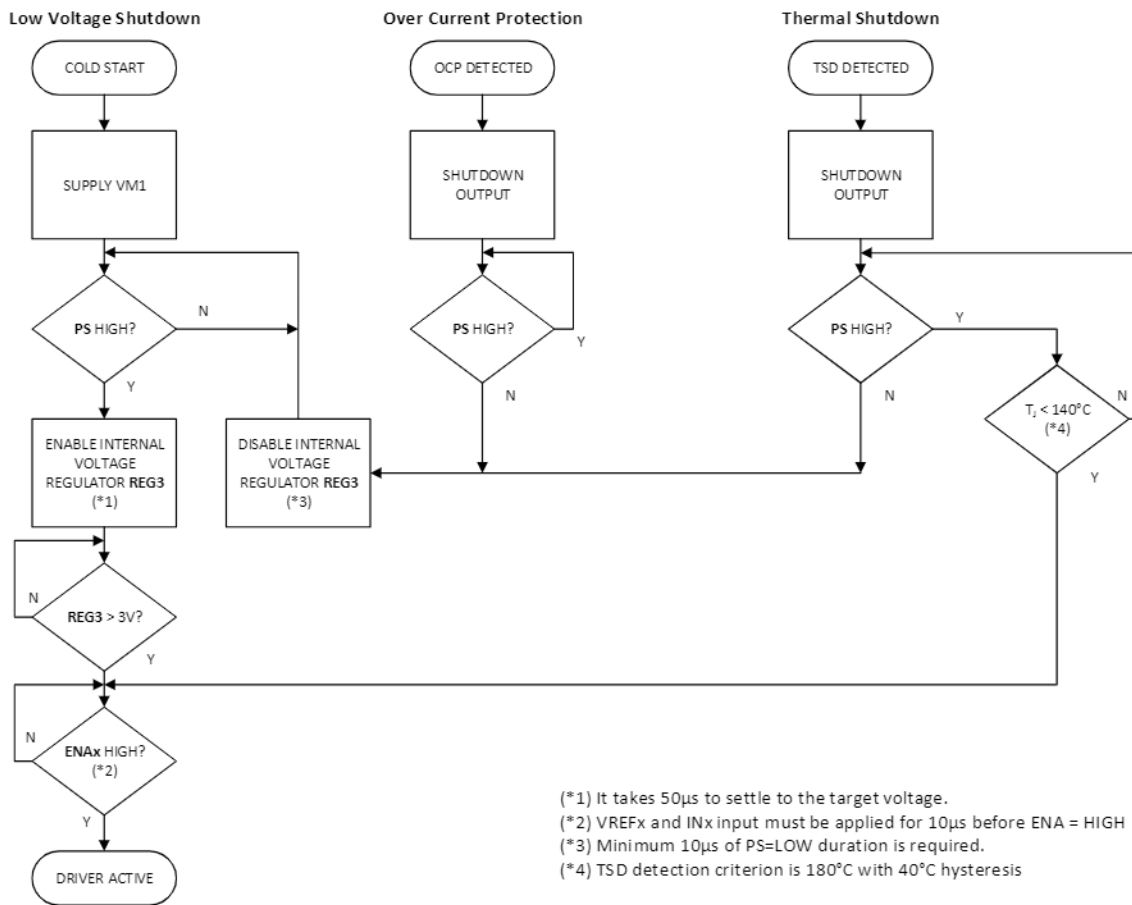

Figure 33. POR and fault handling sequence

**System Protection Functions**

The LV8714 has built-in protection functions such as over-current (OCP), over-temperature (Thermal shutdown, TSD), and under-voltage (Low-voltage shutdown, LVS) protections. These integrated

protections make the LV8714 based system solution highly reliable without need for any external protection circuit. Table 8 shows summary of LV8714 protection functions with recovery mechanisms.

Priority	Fault Event	Condition	OUTxx	Logic	Regulator	Recovery
1	Low Voltage Shutdown LVS	VREG3 < 2.6V	OFF	Reset	< 2.6V	VM1 ≥ 4.0V
2	Thermal Shutdown TSD	Junction temperature > 180°C	OFF	Active	ON	Auto-recover when Tj ≤ 140°C
3	Over-current Protection OCP	Upper side FET current > 2.6A Lower side FET current > 2.0A	OFF	Active	ON	Toggle PS input High → Low (≥10μs) → High

Table 8: Summary of LV8714 protection functions with recovery mechanisms

## Low Voltage Shutdown (LVS)

The integrated LVS protection enables safe shutdown of the system when the VM1 drops. The VREG3 voltage is monitored and the LVS is activated when the VREG3 voltage drops below 2.6V (typ.). It turns off output FETs and logic circuits are put into the reset state. The LV8714 recovers from the LVS automatically when  $VM1 \geq 4V$ .

## Thermal Shutdown (TSD)

The built-in TSD protection prevents damage to the LV8714 from excessive heat. To avoid false trigger, the TSD protection is activated when the die  $T_J$  exceeds 180°C. Once activated, it shuts down output FETs while keeping the rest of circuit in the active state. When  $T_J$

falls below 140°C, the output stage is reactivated under control of input signals INx, and ENAx.

## Over-current Protection (OCP)

The on-chip OCP protection of the LV8714 triggers when current above the threshold is detected internally. Once detected for 2 $\mu$ s, output FETs are turned off and the internal timer is triggered to count 128 $\mu$ s (typ.) of the timer latch period. At the end of the timer latch period, output FETs are turned on again 2 $\mu$ s. If during this time, over-current is detected again, then the fault is latched and FETs are turned off. FETs can now be turned on again only when over-current condition is removed and the PS pin is toggled (High -> Low ( $\geq 10\mu$ s) -> High). Timing chart of the OCP is as shown in Figure 34.

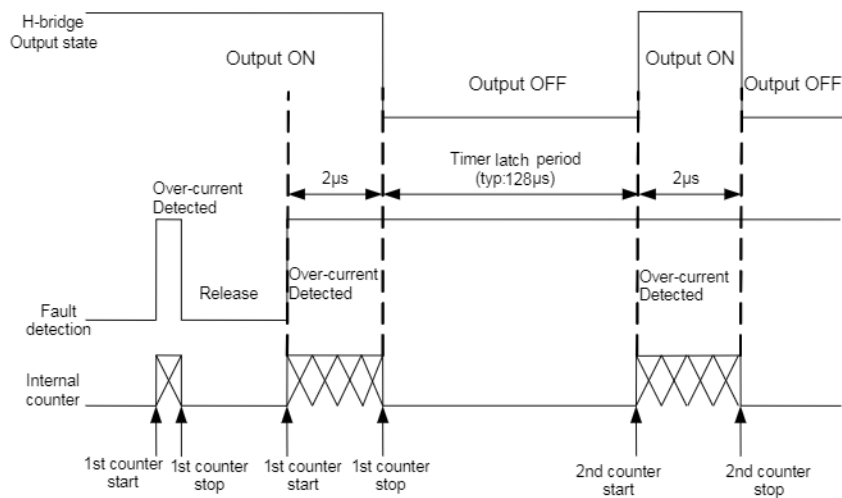

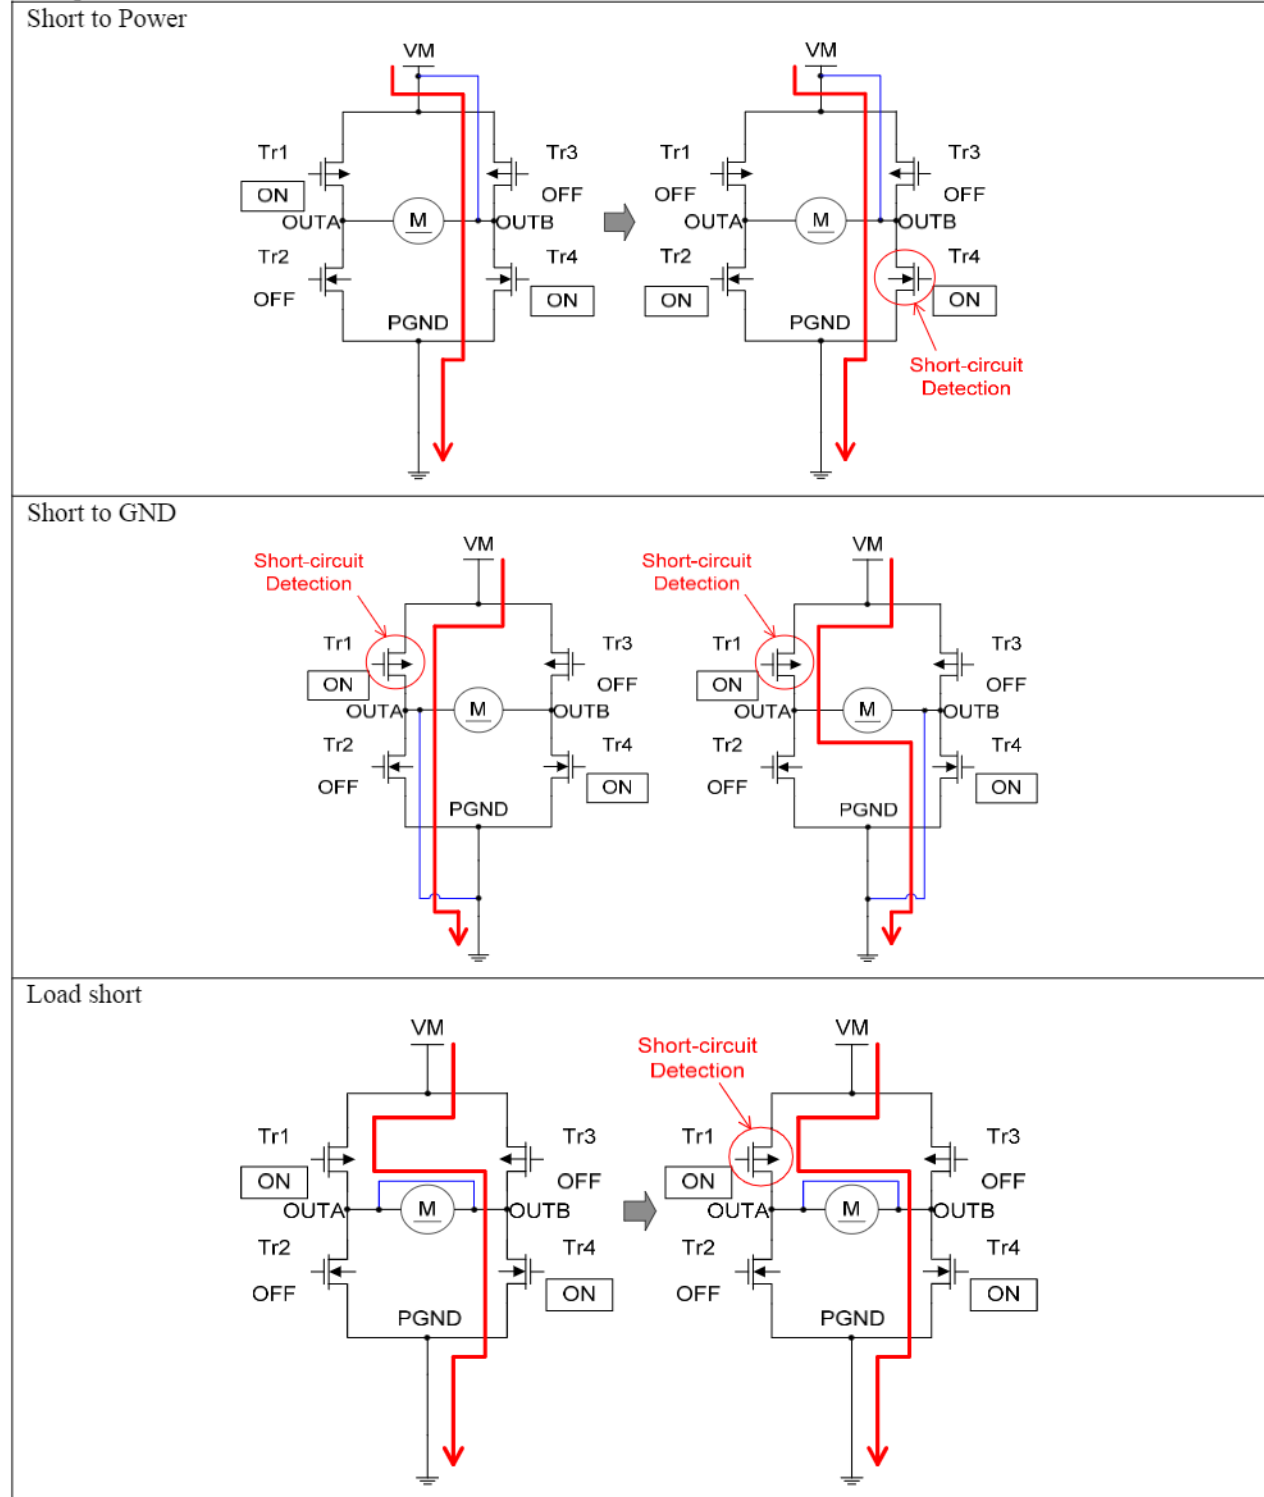

Figure 34. Timing Chart of OCP

Example of Over-current Detection:

**PCB GUIDELINES**

**VM and Ground Routing**

Make sure to short-circuit VM1, VM2, VM3 and VM4 externally by a low impedance route on one side of PCB. As high current flows into PGND, connect it to GND through a low impedance route.

**Exposed Pad**

The exposed pad is connected to the frame of the LV8714. Therefore, do not connect it to anywhere else other than ground. If GND and PGND are in the same plane, connect the exposed pad to the ground plane. Else, if GND and PGND are separated, connect the exposed pad to GND.

**NC Pin Utilization**

NC pins are not connected internally inside the LV8714. If the power track that is connected to VM, outputs and GND is wide, the power track can be connected to NC pins.

**Thermal Test Conditions**

Size: 90mm × 90mm × 1.6mm (four layer PCB)

Material: Glass epoxy

Copper wiring density: L1 = 80% / L4 = 85%

Second layer is VM power supply layer.

Third layer is GND layer

Figure 35. Pattern Diagram of Top and Bottom Layer

**Recommendation**

The thermal data provided is for the thermal test condition where 90% or more of the exposed die pad is soldered.

It is recommended to derate critical rating parameters for a safe design. Electrical parameters that are recommended to be derated are operating voltage, operating current, junction temperature, and device power dissipation. The recommended derating for a safe design is as shown below:

- Maximum 80% or less for operating voltage

- Maximum 80% or less for operating current
- Maximum 80% or less for junction temperature

Check solder joints and verify reliability of solder joints for critical areas such as exposed die pad, power pins and grounds.

Any void or deterioration, if observed, in solder joint of these critical areas parts, may cause deterioration in thermal conduction and that may lead to thermal destruction of the device.
