ecoSwitch[™] Advanced Load Management

Controlled Load Switch with Low RON

NCP45650, NCP45651

The NCP4565x series of load management devices provide a component and area-reducing solution for efficient power domain switching with inrush current limit via soft start. These devices are designed to integrate control and driver functionality with a high performance low on-resistance power MOSFET in a single package. This cost effective solution is ideal for power management and disconnect functions in USB ports requiring low power consumption in a small footprint.

Features

- Advanced Controller with Charge Pump
- Integrated N-Channel MOSFET with Low RON
- Soft-Start via Controlled Slew Rate
- Adjustable Slew Rate Control
- Power Good Output
- Thermal Shutdown
- Under Voltage Lockout
- Over Current Protection
- Input Voltage Range 1 V to 13.5 V
- Extremely Low Standby Current
- Load Bleed (NCP45650) No Load Bleed (NCP45651)
- This is a Pb–Free Device

Typical Applications

- Notebook and Tablet Computers
- Handheld & Mobile Electronics
- Portable Medical Devices
- Hard Drives
- Peripheral Ports

Table 1. PIN DESCRIPTION

Pin	Name	Function
1, 13	V _{IN}	Input voltage (1.5 V – 13.5 V)
2	EN	Active-high digital input used to turn on the MOSFET driver, pin has an internal pull down resistor to GND
3	OCP	Over-current protection trip point adjustment made with a voltage applied (0 V – 1.0 V), pin has an internal pull up resistor (250 k Ω +/-20%) to EN; float if over-current protection is not needed
4	V _{CC}	Driver supply voltage (3.0 V – 5.5 V)
5	GND	Driver ground
6	PG	Active-high, open-drain output that indicates when the gate of the MOSFET is fully charged, external pull up resistor $\ge 100 \text{ k}\Omega$ to an external voltage source required; float if not used.
7	SR	Slew rate adjustment made with an external capacitor to GND; float if not used
8 – 12	V _{OUT}	Source of MOSFET connected to load. Includes an internal bleed resistor to GND

Stresses exceeding those listed in the Maximum Ratings table may damage the device. If any of these limits are exceeded, device functionality should not be assumed, damage may occur and reliability may be affected.

1. PG is an open-drain output that requires an external pull up resistor $\ge 1 \text{ k}\Omega$ to an external voltage source.

2. Surface-mounted on FR4 board using the minimum recommended pad size, 1 oz Cu. SC protection will engage before max current is reached. 3. Tested by the following methods @ $T_A = 25^{\circ}C$:

ESD Human Body Model tested per JESD22-A114

- ESD Charged Device Model per ESD STM5.3.1
- Latch-up Current tested per JESD78

Rating is for all pins except for V_{IN} and V_{OUT} which are tied to the internal MOSFET's Drain and Source. Typical MOSFET ESD performance for V_{IN} and V_{OUT} should be expected and these devices should be treated as ESD sensitive.

APPLICATIONS INFORMATION

Power Sequencing

The NCP4565x will function with any power sequence, but the output turn-on delay and slew rate performance may vary from what is specified. To achieve the specified performance, there are two recommended power sequences:

- 1. $V_{CC} \rightarrow V_{IN} \rightarrow V_{EN}$
- 2. $V_{IN} \rightarrow V_{CC} \rightarrow V_{EN}$

 V_{CC} must be at 2 V or higher when EN is asserted to ensure proper operation.

Enable Control

The NCP4565x allows for enabling the MOSFET in an active-high configuration. When the EN pin is at a logic high level and the V_{CC} supply pin has an adequate voltage applied, the MOSFET will be enabled. Similarly, when the EN pin is at a logic low level, the MOSFET will be disabled. After disabling the NCP4565x at least 400 ms must pass before EN is enabled again to ensure proper slew rate. An internal pull down resistor to ground on the EN pin ensures that the MOSFET will be disabled when not being driven.

Load Bleed

The NCP45650 device has an on-chip bleed resistor that is used to bleed the charge off of the load to ground after the MOSFET has been disabled. In series with the bleed resistor is a bleed switch that is enabled whenever the MOSFET is disabled. Delays are added to the enable of this switch to ensure that both the MOSFET and the bleed switch are not concurrently active. The NCP45651 does not include the load bleed function.

Over-Current and Short-Circuit Protection

The NCP4565x devices are equipped with short-circuit protection and an optional over-current protection that are used to help protect the part and the system from a sudden high-current event, such as the output, V_{OUT} , being shorted to ground. This circuitry is only active when the gate of the MOSFET is fully driven.

Once active, the circuitry monitors the difference in the voltage on the V_{IN} pin and the voltage on the V_{OUT} pin. When the difference is equal to the short-circuit protection threshold voltage, the MOSFET is immediately turned off and for the NCP45650 the load bleed is activated. The part remains latched in this off state until the V_{CC} - supply voltage is cycled. When latched off the behavior of the part if EN is toggled is not defined. After the V_{CC} supply voltage is cycled and EN is high, the MOSFET will be turned on in a controlled fashion with the normal output turn-on delay and slew rate.

The over-current trip point can be enabled to allow for protection before the short-circuit threshold. If this lower threshold is not needed, then OCP can be left floating. By tying the OCP pin to ground the NCP4565x will enable the over-current protection. In the event the OCP threshold is exceeded, the MOSFET will shut down after the blanking time if the voltage difference remains greater than the threshold. Like the short–circuit protection, the part remains latched in this off state until the V_{CC} – supply voltage is cycled. When latched off the behavior of the part if EN is toggled is not defined. After the V_{CC} supply voltage is cycled and EN is high, the MOSFET will be turned on in a controlled fashion with the normal output turn–on delay and slew rate.

Thermal Shutdown

The thermal shutdown of the NCP4565x devices protect the part from internally or externally generated excessive temperatures. This circuitry is disabled when EN is not active to reduce standby current. When an over-temperature condition is detected, the MOSFET is immediately turned off and the load bleed is activated.

The part comes out of thermal shutdown when the junction temperature decreases to a safe operating temperature as dictated by the thermal hysteresis. Upon exiting a thermal shutdown state, and if EN remains active, the MOSFET will be turned on in a controlled fashion with the normal output turn–on delay and slew rate.

Under Voltage Lockout

The under voltage lockout of the NCP45655x devices turn the MOSFET off and activate the load bleed when the input voltage, V_{IN} , drops below the under voltage lockout threshold. This circuitry is disabled when EN is not active to reduce standby current.

If the V_{IN} voltage rises above the under voltage lockout threshold, and EN remains active, the MOSFET will be turned on in a controlled fashion with the normal output turn–on delay and slew rate.

Power Good

The NCP4565x devices have a power good output (PG) that can be used to indicate when the gate of the MOSFET is fully charged. The PG pin is an active-high, open-drain output that requires an external pull up resistor, RPG, greater than or equal to 1k to an external voltage source that is compatible with input levels of all devices connected to this pin.

The power good output can be used as the enable signal for other active-high devices in the system. This allows for guaranteed by design power sequencing and reduces the number of enable signals needed from the system controller. If the power good feature is not used in the application, the PG pin should be tied to GND.

Slew Rate Control

The NCP4565x devices are equipped with controlled output slew rate which provides soft start functionality. This limits the inrush current caused by capacitor charging and enables these devices to be used in hot swapping applications.

The slew rate can be decreased with an external capacitor added between the SR pin and ground. With an external

capacitor present, the slew rate can be determined by the following equation:

Slew Rate =
$$\frac{K_{SR}}{C_{SR}}$$
 [V/s] (eq. 1)

Where K_{SR} is the specified slew rate control constant, found on page 3, and C_{SR} is the capacitor added between the SR pin and ground. Note that the slew rate of the device will always be the lower of the default slew rate and the adjusted slew rate. Therefore, if the C_{SR} is not large enough to decrease the slew rate more than the specified default value, the slew rate of the device will be the default value.

Capacitive Load

The peak in-rush current associated with the initial charging of the application load capacitance needs to stay below the specified Imax. CL (capacitive load) should be less then Cmax as defined by the following equation:

$$C_{max} = \frac{I_{max}}{SR_{typ}}$$

Where Imax is the maximum load current, and SRtyp is the typical default slew rate when no external load capacitor is added to the SR pin.

OFF to ON Transition Energy Dissipation

The energy dissipation due to load current traveling from VIN to VOUT is very low during steady state operation due to the low RON. When the EN signal is asserted high, the load switch transitions from an OFF state to an ON state. During this time, the resistance from V_{IN} to V_{OUT} transitions from high impedance to R_{ON} , and additional energy is dissipated in the device for a short period of time. The worst case energy dissipated during the OFF to ON transition can be approximated by the following equation:

$$\mathsf{E} = 0.5 \cdot \mathsf{V}_{\mathsf{IN}} \cdot \left(\mathsf{I}_{\mathsf{INRUSH}} + 0.8 \cdot \mathsf{I}_{\mathsf{LOAD}}\right) \cdot \mathsf{dt} \qquad (\mathsf{eq. 2})$$

Where V_{IN} is the voltage on the V_{IN} pin, I_{INRUSH} is the inrush current caused by capacitive loading on V_{OUT} , and dt is the time it takes V_{OUT} to rise from 0 V to V_{IN} . I_{INRUSH} can be calculated using the following equation:

$$I_{\text{INRUSH}} = \frac{\text{dv}}{\text{dt}} \cdot C_{\text{L}} \qquad (\text{eq. 3})$$

Where dv/dt is the programmed slew rate, and C_L is the capacitive loading on V_{OUT} . To prevent thermal lockout or damage to the device, the energy dissipated during the OFF to ON transition should be limited to E_{TRANS} listed in Absolute Maximum Ratings.

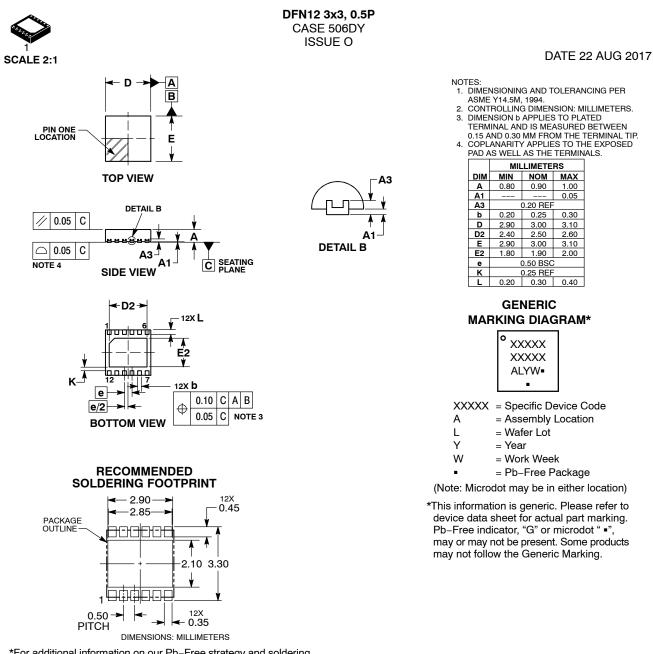

ecoSWITCH LAYOUT GUIDELINES

Electrical Layout Considerations

Correct physical PCB layout is important for proper low noise accurate operation of all ecoSWITCH products.

Power Planes: The ecoSWITCH is optimized for extremely low Ron resistance, however, improper PCB layout can substantially increase source to load series resistance by adding PCB board parasitic resistance. Solid connections to the VIN and VOUT pins of the ecoSWITCH to copper planes should be used to achieve low series resistance and good thermal dissipation. The ecoSWITCH requires ample heat dissipation for correct thermal lockout operation. The internal FET dissipates load condition dependent amounts of power in the milliseconds following the rising edge of enable, and providing good thermal conduction from the packaging to the board is critical. Direct coupling of VIN to VOUT should be avoided, as this will adversely affect slew rates.
