

AT25XE321D

32 Mbit, 1.65V - 3.6V Range
SPI Serial Flash Memory with Multi-I/O Support

Features

- Voltage Range: 1.65V - 3.6V
- 32 Mbit (4M x 8) Flash Memory
- Flexible 256-byte page erase architecture
- Serial Peripheral Interface (SPI) compatible
 - Supports SPI modes 0 and 3
 - Supports SPI single mode operation (1-1-1)
 - Supports dual output operation (1-1-2)
 - Supports quad output operation (1-1-4)
 - Supports quad XiP operation (1-4-4 and 0-4-4)
- 104 MHz maximum operating frequency
 - Clock-to-output of 8 ns
- Flexible, optimized erase architecture for code + data storage applications
 - Uniform 256-Byte page erase
 - Uniform 4-KByte block erase
 - Uniform 32-KByte block erase
 - Uniform 64-KByte block erase
 - Full chip erase
- Flexible non-volatile block protection
- 1 x 128-byte factory-programmed unique identifier
- 3 x 128-byte, One Time Programmable (OTP) security registers
- Flexible programming
 - Byte/Page program (1 to 256 Bytes)
 - Single command page buffer direct Read-Modify-Write (page write with inclusive erase)
 - Flexible 256-byte SRAM page buffer operation
 - Sequential program mode capability
- Erase program suspend resume
- Software controlled reset and stop commands
- Hardware reset option (via /HOLD pin)
- JEDEC hardware reset
- Low battery detect circuit
- Active interrupt device status capability
- Non-volatile status register configuration option
- JEDEC standard manufacturer and device ID read methodology
- Serial Flash Discoverable Parameters (SFDP) version 1.6
- Low power dissipation:
 - 24 μ A standby current (typical)
 - 6 μ A Deep Power-Down (DPD) current (typical)
 - 7 nA Ultra Deep Power Down (UDPD) current (typical)
 - 7.6 mA active read current (1-1-1 — 104 MHz)
 - 8.6 mA program current
 - 9.3 mA erase current
- User configurable and auto I/O pin drive levels
- Endurance
 - 100,000 program/erase cycles
- Data Retention
 - 20 years
- -40 °C to +85 °C operation
- Industry standard green (Pb/Halide-free/RoHS Compliant) Package Options
 - 8-lead SOIC (150-mil)
 - 8-lead SOIC (208-mil)
 - 8-pad Ultra-thin DFN (5 x 6 x 0.6 mm)
 - 12-ball WLCSP (3 x 2 x 3 ball matrix)
 - Die/Wafer — Contact Adesto for more information

Adesto

1. Product Overview

The Adesto® AT25XE321D is a serial interface Flash memory device designed for use in a wide variety of high-volume consumer and connected applications. It is optimized for low-energy applications and can be operated using modern Lithium battery technologies over a wide input voltage range of 1.65V - 3.6V.

The AT25XE321D is ideally suited for systems in which program code is shadowed from Flash memory into embedded or external RAM (code shadow) for execution, and where small amounts of data are stored and updated locally in the Flash memory.

The erase block sizes of the AT25XE321D have been optimized to meet the needs of today's code and data storage applications. The device supports 256-byte page erase, as well as 4 KiloByte (KB), 32 KB, and 64 KB block erase operations and a full-chip erase. By optimizing the size of the erase blocks, the memory space can be used much more efficiently.

The device also includes an active interrupt allowing the host to sleep during lengthy programming or erase operations, allowing the memory device to wake the MCU when completed, and optimized energy consumption and class-leading 7nA ultra-deep power-down modes. The device contains four specialized 128-byte One-Time Programmable (OTP) security registers that can be used to store a unique device ID and locked key storage.

Specifically designed for use in a wide variety of systems, the AT25XE321D supports read, program, and erase operations. No separate voltage is required for programming and erasing.

Throughout this document, the term Multi-I/O is used generically to refer to all of the multiple I/O modes, including dual, quad, and XiP.

2. Package Pinouts

Figure 2-1 show the package pinouts for the following devices. Note that the Die Wafer Scale option is not shown:

3. Block Diagram

Figure 3-1 shows a block diagram of the AT25XE321D device. The *Interface Control Logic* block connects to external device through a set of pins. The state of these pins is distributed *Interface Control Logic* block to other blocks as necessary. The design also contains a 32 Mbit serial Flash memory array, a 256-byte SRAM buffer, and an *I/O Interface Unit* that operates depending on the type of data transfer mode.

Figure 3-1. Block Diagram

4. Pin Descriptions

Table 4-1. Pin Descriptions

Symbol	Name and Function	Asserted State	Type
$\overline{\text{CS}}$	<p>CHIP SELECT: Asserting the $\overline{\text{CS}}$ pin selects the device. When the $\overline{\text{CS}}$ pin is deasserted, the device is deselected and normally be placed in standby mode (not Deep Power-Down mode), and the SO pin is in a high-impedance state. When the device is deselected, data will not be accepted on the SI pin.</p> <p>A high-to-low transition on the $\overline{\text{CS}}$ pin is required to start an operation, and a low-to-high transition is required to end an operation. When ending an internally self-timed operation such as a program or erase cycle, the device will not enter the standby mode until the completion of the operation.</p>	Low	Input
SCK	<p>SERIAL CLOCK: This pin is used to provide a clock to the device and is used to control the flow of data to and from the device. Command, address, and input data present on the SI pin is always latched in on the rising edge of SCK, while output data on the SO pin is always clocked out on the falling edge of SCK.</p>	-	Input
SI (I/O ₀)	<p>SERIAL INPUT: The SI pin is used to shift data into the device. The SI pin is used for all data input including command and address sequences. Data on the SI pin is always latched in on the rising edge of SCK.</p> <p>With the Multi I/O Read commands, the SI pin becomes an output pin (I/O₀) in conjunction with other pins to allow either two or four bits of data on (I/O_{1:0} or I/O_{3:0}) to be clocked out on every falling edge of SCK.</p> <p>Data present on the SI pin is ignored whenever the device is deselected ($\overline{\text{CS}}$ is deasserted and the device is in the reset condition).</p>	-	Input/ Output
SO (I/O ₁)	<p>SERIAL OUTPUT: The SO pin is used to shift data out from the device. Data on the SO pin is always clocked out on the falling edge of SCK.</p> <p>With the Multi I/O Read commands, the SO pin remains an output pin (I/O₁) in conjunction with other pins to allow either two or four bits of data on (I/O_{1:0} or I/O_{3:0}) to be clocked out on every falling edge of SCK.</p> <p>The SO pin is in a high-impedance state whenever the device is deselected ($\overline{\text{CS}}$ is deasserted and the device is in the reset condition).</p>	-	Input/ Output
$\overline{\text{WP}}$ (I/O ₂)	<p>WRITE PROTECT: The $\overline{\text{WP}}$ pin controls the hardware locking feature of the device. When set, this bit prevents the Status Register from being written. This bit is used in conjunction with other Status Register bits (CMPRT, BPSIZE, TB, and BP[2:0]) to provide hardware protection of the memory array.</p> <p>The $\overline{\text{WP}}$ pin is internally pulled-high and may be left floating if hardware controlled protection will not be used. However, it is recommended that the $\overline{\text{WP}}$ pin also be externally connected to V_{CC} whenever possible.</p> <p>When the QE bit in Status Register 2 is set, enabling quad mode (Output or I/O), the WP pin becomes bidirectional and functions as the IO₂ pin used to transmit address and/or data, depending on the transfer mode.</p>	Low	Input/ Output

Table 4-1. Pin Descriptions (continued)

Symbol	Name and Function	Asserted State	Type
$\overline{\text{HOLD/RESET}}$ (I/O ₃)	<p>HOLD / RESET: The $\overline{\text{HOLD}}$ pin is used to temporarily pause serial communication without deselecting or resetting the device. While the $\overline{\text{HOLD}}$ pin is asserted, transitions on the SCK pin and data on the SI pin are ignored and the SO pin is placed in a high-impedance state. The $\overline{\text{CS}}$ pin must be asserted, and the SCK pin must be in the low state in order for a Hold condition to start. A Hold condition pauses serial communication only and does not have an effect on internally self-timed operations such as a program or erase cycle. With the Quad Output Byte/Page Program command, the $\overline{\text{HOLD}}$ pin becomes an input pin (I/O₃) and, along with other pins, allows four bits (on I/O_{3,0}) of data to be clocked in on every rising edge of SCK. With the Quad-Output Read commands, the $\overline{\text{HOLD}}$ Pin becomes an output pin (I/O₃) in conjunction with other pins to allow four bits of data on (I/O_{3,0}) to be clocked in on every falling edge of SCK.</p> <p>To maintain consistency with the SPI nomenclature, the $\overline{\text{HOLD}}$ (I/O₃) pin is referenced as the $\overline{\text{HOLD}}$ pin unless specifically addressing the Quad Output mode in which case it is referenced as I/O₃.</p> <p>The $\overline{\text{HOLD}}$ pin is internally pulled-high and may be left floating if the Hold function is not used. However, it is recommended that the $\overline{\text{HOLD}}$ pin also be externally connected to V_{CC} whenever possible.</p> <p>When the QE bit in the Status register is cleared, the IO₃ pin can be configured either as a $\overline{\text{HOLD}}$ pin or as a $\overline{\text{RESET}}$ pin depending on the state of the $\overline{\text{HOLD/RESET}}$ bit 7 in Status Register 3. Note that when the QE bit is set, the $\overline{\text{HOLD}}$ or $\overline{\text{RESET}}$ function is not available as this pin is used to transfer data.</p>	Low	Input/Output
V _{CC}	<p>DEVICE POWER SUPPLY: The V_{CC} pin is used to supply the source voltage to the device. Operations at invalid V_{CC} voltages may produce spurious results and should not be attempted.</p>	-	Power
GND	<p>GROUND: The ground reference for the power supply. GND should be connected to the system ground.</p>	-	Power

5. Device Operation

This section describes the various data transfer modes supported by the device, as well as other system operations.

5.1 Data Transfer Modes

The JEDEC specification uses a numerical system to indicate the type of transfer for a given command. The nomenclature for this system is defined as (x-y-z) to indicate the number of active pins used for the command (x), address (y), and data (z). For an example, a designation of 1-1-2 indicates that one pin (SI) is used to transfer the command, one pin (SI) for the address, and two pins (SI and SO) for the data. The AT25XE321D supports the following transfer types.

Table 5-2. Bus Transfer Types

Transfer Type	Transfer Name	Command	Pin(s) Used for Command	Address	Pin(s) Used for Address	Data	Pin(s) Used for Data
1-0-0	SPI	Yes	SI	No	--	No	--
1-1-0	SPI	Yes	SI	Yes	SI	No	--
1-0-1	SPI	Yes	SI	No	--	Yes	SI (write) SO (read)
1-1-1	SPI	Yes	SI	Yes	SI	Yes	SI (write) SO (read)
1-1-2	Dual Output	Yes	SI	Yes	SI	Yes	SI, SO
1-1-4	Quad Output	Yes	SI	Yes	SI	Yes	SI, SO, \overline{WP} , \overline{HOLD}
1-4-4	Quad I/O	Yes	SI	Yes	SI, SO, \overline{WP} , \overline{HOLD}	Yes	SI, SO, \overline{WP} , \overline{HOLD}
0-4-4	XiP	No	--	Yes	SI, SO, \overline{WP} , \overline{HOLD}	Yes	SI, SO, \overline{WP} , \overline{HOLD}

As shown in the table above, the AT25XE321D supports the following transfer formats. These formats are described in the following subsections:

- Standard SPI Operation
- Dual Output Operation
- Quad Output Operation
- Quad I/O Operation
- XiP Operation

5.2 Standard SPI Operation

Standard SPI transfers are divided into three elements; command, address, and data. SPI mode support the following four transfer types as described in [Table 5-2](#).

- Command only, no address or data (1-0-0)
- Command and address only, no data (1-1-0)
- Command and data only, no address (1-0-1)
- Command, address, and data (1-1-1)

For standard SPI transfers, command and address are always transferred on the SI pin. For write operations, data is also transferred on the SI pin. For read operations, data is transferred on the SO pin.

The AT25XE321D supports the two most common SPI modes, 0 and 3, meaning that data is always latched on the rising edge of SCK and always output on the falling edge of SCK.

5.2.1 Command Only, No Address or Data (1-0-0)

The following diagram shows a command-only transfer. In this type of transfer no address or data are required. An example would be the *Chip Erase* (60h/C7h) command. A 1-0-0 transfer type is shown in [Figure 5-2](#).

Figure 5-2. SPI Transfer — Command Only

5.2.2 Command and Address Only, No Data (1-1-0)

The following diagram shows a transfer with command and address only. In this type of transfer no data is required. An example would be the *Block Erase* (20h) command, where the address indicates the location of the block to be erased.

The 1-1-0 transfer type is shown in [Figure 5-3](#).

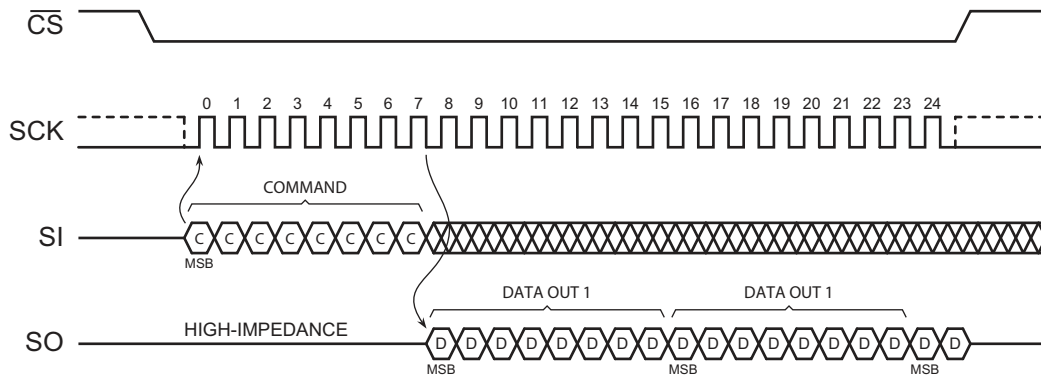

Figure 5-3. SPI Transfer — Command and Address Only

5.2.3 Command and Data Only, No Address (1-0-1)

The following diagram shows a transfer with command and data only. In this type of transfer no address is required. An example would be the *Status Register Read* (05h/35h/15h) and *Status Register Write* (01h/31h/11h) commands, where the command itself indicates the location of the register. The 1-0-1 transfer type for a read operation is shown in [Figure 5-4](#).

Figure 5-4. SPI Transfer — Command and Data Only — Read Operation

The 1-0-1 transfer type for a write operation is shown in [Figure 5-5](#).

Figure 5-5. SPI Transfer — Command and Data Only — Write Operation

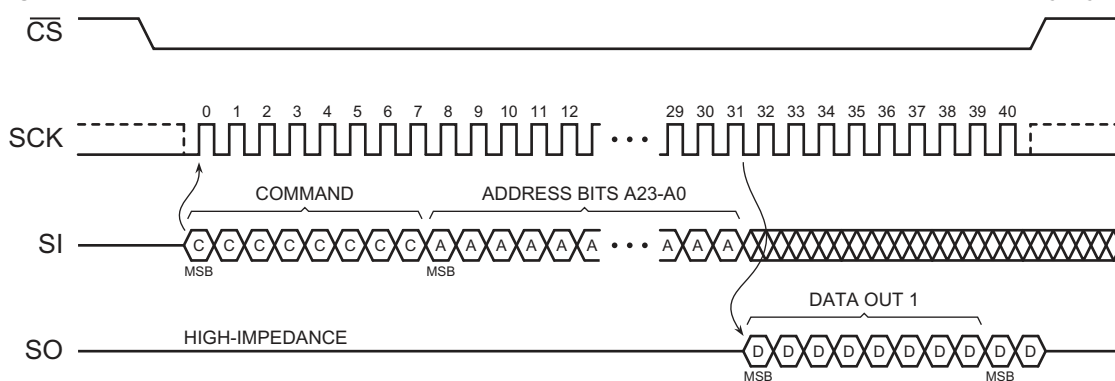

5.2.4 Command, Address, and Data (1-1-1)

The following diagram shows a command, address, and data transfer. In this type of transfer the command and address are followed by one or more data types, depending on the command type.

Note that this type of transfer may contain one or more dummy bytes between the end of the address and the beginning of the data output depending on the type of command. Refer to the command table in Section 7 for more information.

The 1-1-1 transfer type for a read operation without dummy bytes is shown in [Figure 5-6](#). An example would be the *Read Array* (03h) command.

Figure 5-6. SPI Transfer — Command, Address, and Data — Read Operation with No Dummy Bytes

The 1-1-1 transfer type for a read operation with dummy bytes is shown in [Figure 5-7](#). An example would be the *Fast Read Array* (0Bh) command. Note that eight dummy clocks are shown in the figure below for illustration purposes only. More than eight clocks may be required depending on the type of operation and operating frequency.

Figure 5-7. SPI Transfer — Command, Address, and Data — Read Operation with Dummy Bytes

The 1-1-1 transfer type for a write operation is shown in [Figure 5-8](#). An example would be the Byte/Page Program (02h) command.

Figure 5-8. SPI Transfer — Command, Address, and Data — Write Operation

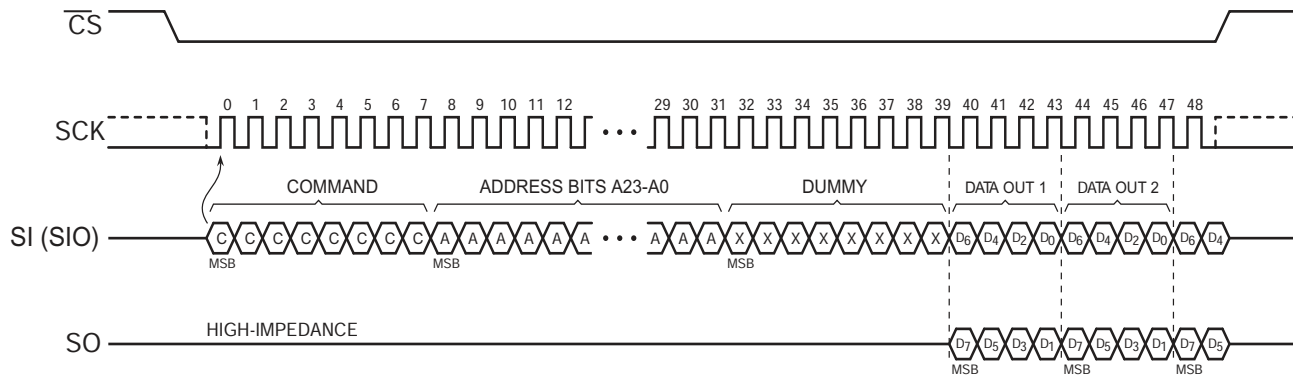

5.3 Dual Output Operation (1-1-2)

The AT25XE321D supports the Dual Output (1-1-2) transfer type which enhances overall throughput over the standard SPI mode. This mode transfer command and address on the SI pin like in SPI mode, but the data is transferred on to the SI and SO pins. This means that only half the number of clocks are required to transfer the data.

A Dual Output read operation is shown in [Figure 5-9](#). An example of this operation would be a *Dual Output Read* (3Bh). Note that this type of transfer may contain one or more dummy bytes between the end of the address and the beginning of the data output depending on the type of command and the operating frequency. Refer to the Command table in Section 7 for more information.

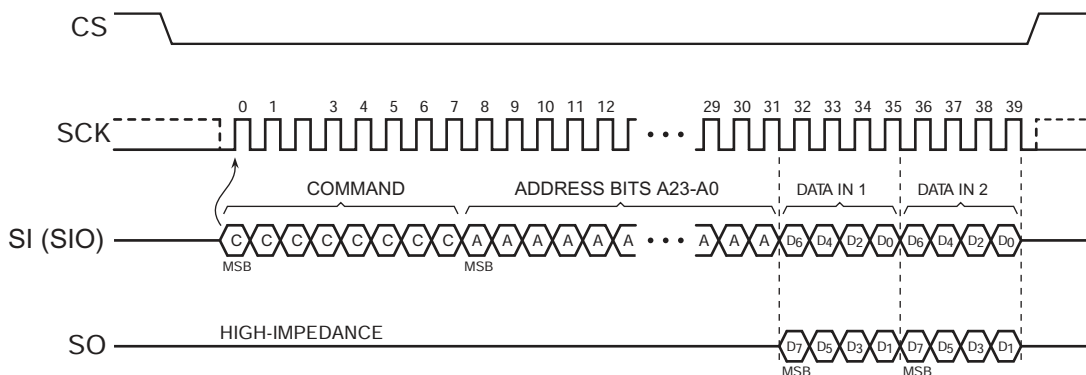

A Dual Output 1-1-2 read operation is shown in [Figure 5-9](#).

Figure 5-9. Dual Output Read — 1-pin Command, 1-Pin Address, and 2-Pin Data

A Dual Output (1-1-2) write operation is shown in [Figure 5-10](#). An example of this operation would be a *Dual Output Byte/Page Program* (A2h).

Figure 5-10. Dual Output Write — 1-pin Command, 1-Pin Address, and 2-Pin Data

5.4 Quad Output Operation (1-1-4)

The AT25XE321D supports the Quad Output mode which enhances overall throughput over the standard SPI and dual operation modes by increasing the data transfer rate. In this mode, data is transferred on four pins; SI, SO, \overline{WP} , and \overline{HOLD} . This means that only 1/4th the number of clocks are required to transfer the data relative to standard SPI mode. This is known as a 1-1-4 transfer which is defined as follows:

- 1-pin command, 1-pin address, and 4-pin data (1-1-4)

In Quad Output mode the command (C) and address (A) are driven to the memory device on the SI (IO₀) pin. During write operations, the SI (IO₀), SO (IO₁), \overline{WP} (IO₂), and \overline{HOLD} (IO₃) pins switched to inputs and the data is driven on all four pins, allowing four data bits to be transferred on every clock. During read operations, once the command and address are transferred on the SI (IO₀) pin, the SI (IO₀), SO (IO₁), \overline{WP} (IO₂), and \overline{HOLD} (IO₃) pins switched to outputs and the data is driven on all four pins, allowing four data bits to be transferred on every clock.

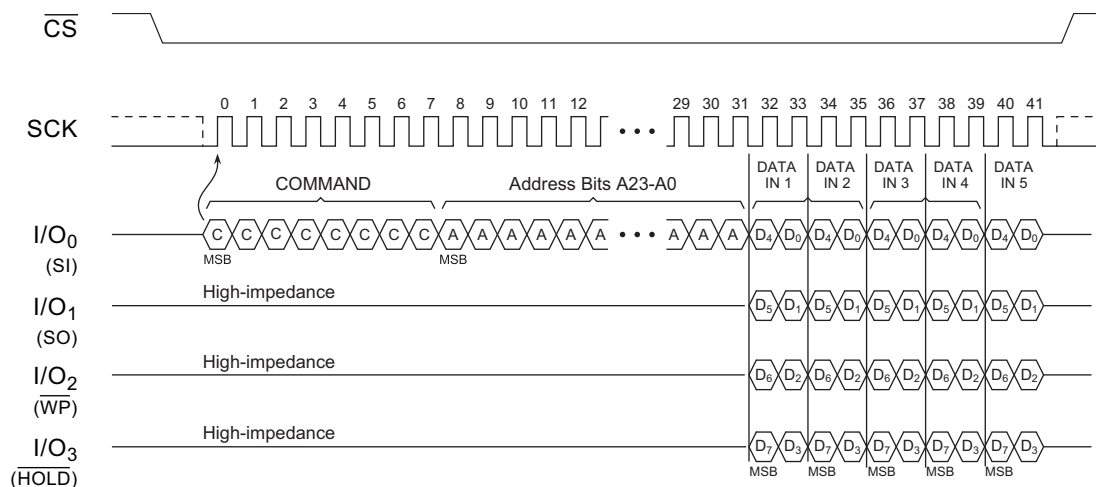

A 1-1-4 Dual Output read operation is shown in [Figure 5-11](#). An example of this operation would be a *Quad Output Read* (6Bh). Note that this type of transfer may contain one or more dummy bytes between the end of the address and the beginning of the data output depending on the type of command and the operating frequency. Refer to the Command table in Section 7 for more information.

Figure 5-11. Quad Output Transfer — 1-Pin Command, 1-Pin Address, and 4-Pin Data — Read Operation

A 1-1-4 Quad Output write operation is shown in [Figure 5-12](#). An example of this operation would be a *Quad Output Byte/Page Program* (32h).

Figure 5-12. Quad Output Transfer — 1-Pin Command, 1-Pin Address, and 4-Pin Data — Write Operation

5.5 Quad I/O Operation (1-4-4)

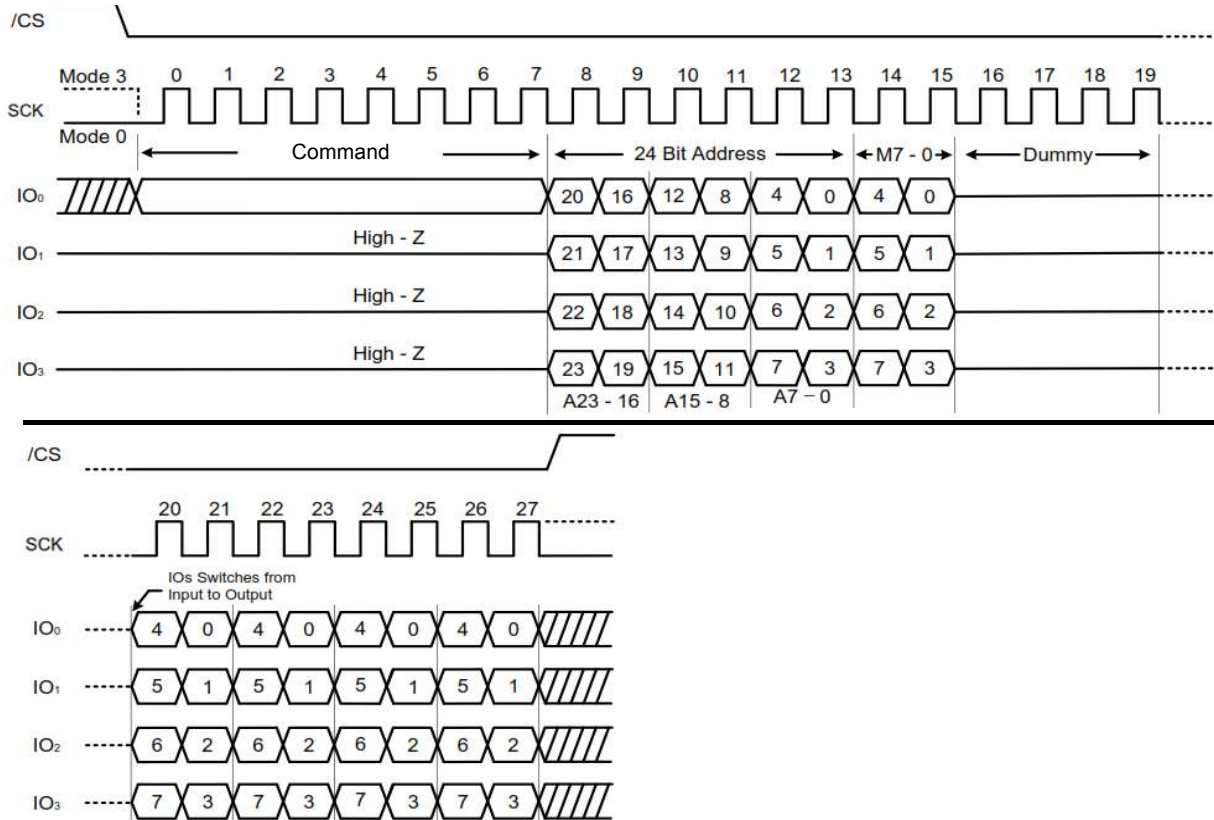

The AT25XE321D supports the Quad I/O mode which enhances overall throughput over the standard SPI and dual operation modes by increasing the data transfer rate. In this mode, address and data are transferred on four pins; SI, SO, \overline{WP} , and \overline{HOLD} . This means that only 1/4th the number of clocks are required to transfer the address and data relative to standard SPI mode. This is known as a 1-4-4 transfer which is defined as follows:

- 1-pin command, 4-pin address, and 4-pin data (1-4-4)

In Quad I/O mode the command (C) is driven to the memory device on the SI (I/O₀) pin. During write operations, the SI (I/O₀), SO (I/O₁), \overline{WP} (I/O₂), and \overline{HOLD} (I/O₃) pins switched to inputs and the address and data are driven on all four pins, allowing four bits to be transferred on every clock. During read operations, once the command is transferred on the SI (I/O₀) pin, address is transferred on the SI (I/O₀), SO (I/O₁), \overline{WP} (I/O₂), and \overline{HOLD} (I/O₃) pins, allowing a 24-bit address to be transferred in only six clocks. Once the address transfer is complete, these pins are switched to outputs and the data is driven on all four pins, allowing four data bits to be transferred on every clock.

A 1-4-4 Quad I/O read operation is shown in Figure 5-11. An example of this operation would be a *Manufacturer/Device ID Read* (94h). Note that this type of transfer may contain one or more dummy bytes between the end of the address and the beginning of the data output depending on the type of command and the operating frequency. Refer to the Command table in Section 7 for more information.

Figure 5-13. Quad I/O Transfer — 1-Pin Command, 4-Pin Address, and 4-Pin Data — Read Operation

5.6 XiP Mode Operation

The XiP mode is similar to the Quad I/O mode in that both the address and data are transferred on all four pins, SI (IO_0), SO (IO_1), \overline{WP} (IO_2), and \overline{HOLD} (IO_3). Using all four pins to transfer address and data allows XiP mode to reduce the overall number of clocks required to complete the operation, thereby streamlining code execution.

The XiP mode is enabled by setting bit 2 (QE) of status register 1, and bit 3 (XiP) of status register 4. The QE bit enables Quad I/O mode, allowing address and data to be transferred on all four pins. Setting the XiP bit enables continuous read mode, allowing subsequent transfers to occur without the need for driving the command each time. Continuous read mode is controlled by mode bits $M[5:4]$ as explained below. Therefore, the initial EBh or E7h command requires the command to be driven, but for subsequent transfers the command is not required.

The XiP mode is only used for the following commands:

- EBh: XiP mode initial read (1-4-4)
- EBh: XiP mode subsequent reads (0-4-4)
- E7h: XiP mode initial read with Doubleword Aligned (DWA) address (1-4-4)
- E7h: XiP mode subsequent reads with DWA address (0-4-4)

As shown above, the only difference between the EBh and E7h commands is that the E7h command is performed only on a double-word aligned address boundary. The EBh command does not have this restriction.

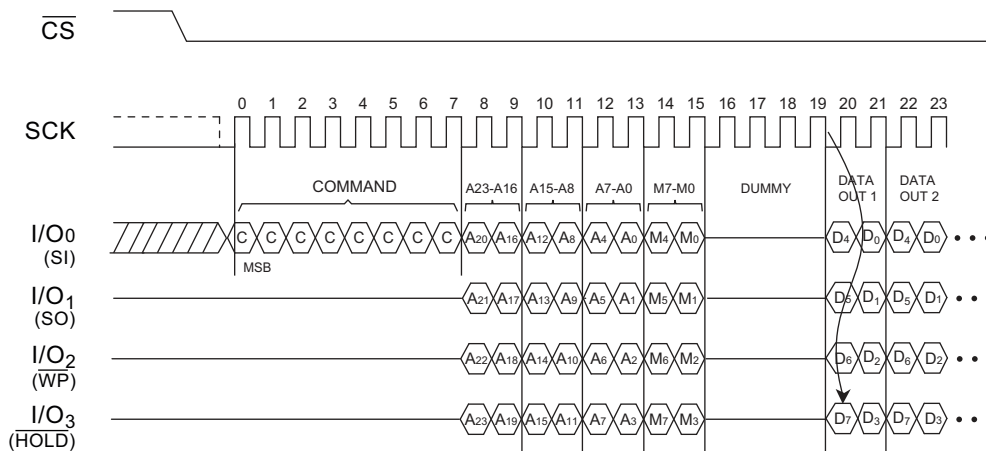

The *Set Burst with Wrap (77h)* command does not access the memory directly, but rather is used in conjunction with the EBh and E7h commands to select 8-, 16-, 32-, or 64-Byte sections within a 256-byte page. The user selects the size by programming the wrap bits as part of the 77h command. Refer to the table in [Section 7.14, Set Burst Wrap \(77h\)](#) for more information.

When the EBh/E7h command is driven onto the bus, the associated data immediately following the address contains eight mode bits, known as M[7:0]. Of these bits, M[5:4] are decoded and used by hardware to determine if the device is in XiP continuous read mode. If the value on M[5:4] equals 2'b10, the device is placed into XiP mode to allow for continuous read operations to occur, meaning that for subsequent operations the command field is not required. Each time a subsequent transfer is made, it contains only the address and mode bits.

Initial Transfer and XiP Mode Detection (M[5:4])

The initial XiP transfer follows the 1-4-4 format, where the EBh or E7h command is transferred on the SI (IO₀) pin, and address and data are transferred on the SI (IO₀), SO (IO₁), \overline{WP} (IO₂), and HOLD (IO₃) pins. Because all four pins are used, the address requires only six clocks to transfer. The initial 1-4-4 XiP mode transfer is shown in [Figure 5-14](#).

Figure 5-14. XiP Transfer — 1-Pin Command, 4-Pin Address, and 4-Pin Data — Initial Read (M[5:4] = 2'b10)

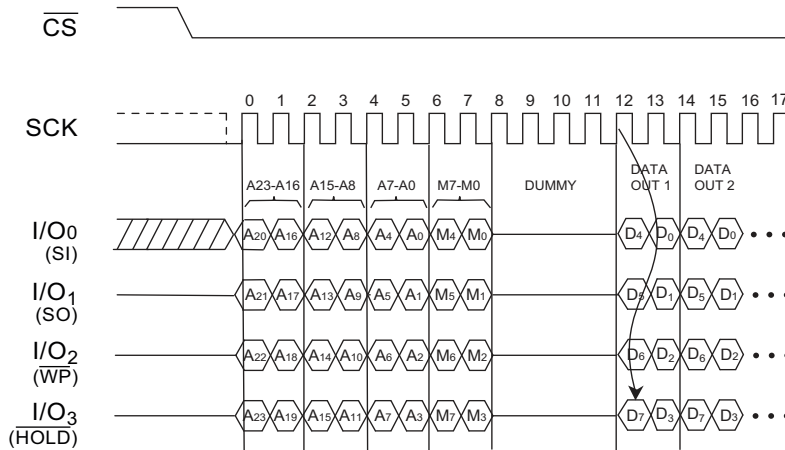

Subsequent Transfers

Once XiP mode is detected, subsequent operations do not require the command to be transferred. After the data stream starts, the user can deassert the \overline{CS} pin. Once \overline{CS} is deasserted, data output is suspended. Once \overline{CS} is again driven low, only the address and M[7:0] mode data are required because the device is already in XiP mode. Each time a new operation is transferred on the bus, hardware decodes the M[7:0] bits. As long as M[5:4] have a value of 2'b10, the device is in XiP mode and it is not necessary to transfer the command. Once M[5:4] \neq 2'b10 (any value other than 2'b10), the operation completes and the device exits XiP mode.

A subsequent 0-4-4 XiP mode transfer is shown in [Figure 5-15](#).

Figure 5-15. XiP Transfer — No Command, 4-Pin Address, and 4-Pin Data — Subsequent Reads ($M[5:4] = 2'b10$)

Set Burst with Wrap

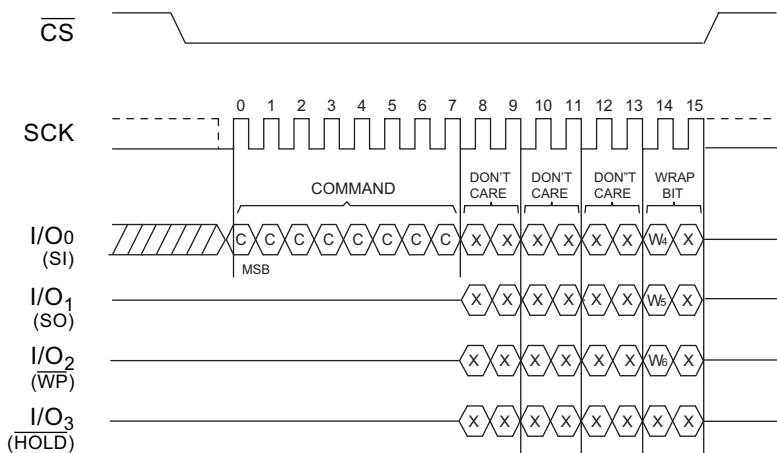

As mentioned above, the *Set Burst with Wrap (77h)* command is used in conjunction with the EBh and E7h commands to select specific sections within a 256-byte page. When this command is transferred, the data field contains 8 wrap bits. Bits 6:4 of this field determine the wrap length, which can be between 8 and 64 bytes. Refer to [Section 7.14, Set Burst Wrap \(77h\)](#) for more information.

Note that when the device receives the EBh/E7h command with $M[5:4] = 2'b10$, then the device enters XiP mode. While in the XiP (0-4-4) mode (see Subsequent Transfers subsection above) the only command that the device can execute are EBh (or E7h). This is mandatory since the command field for subsequent transfers does not exist.

During normal operation, the user sends the 77h command before entering XiP mode. If the user wants to issue a 77h command after XiP mode has been entered (to change the wrap length/properties), they must exit the XiP mode by sending a 0-4-4 command with $M[5:4] \neq 2'b10$. This exits XiP mode. Then the user can issue the 77h command.

The 77h command is a 1-4-4 XiP mode transfer as shown in [Figure 5-16](#).

Figure 5-16. XiP Transfer — 1-Pin Command, 4-Pin Address, and 4-Pin Data — Write Operation

Refer to [Section 7.14, Set Burst Wrap \(77h\)](#) for more information.

5.7 Memory Architecture

The memory array of the AT25XE321D memory array is divided into three levels of granularity comprising of blocks and pages;

- 64 KB blocks
- 32 KB blocks
- 4 KB blocks
- 256 byte pages

The size of the erase blocks is optimized for both code and data storage applications, allowing both code and data segments to reside in their own erase regions.

Figure 5-17 illustrates the breakdown of each level and details the number of pages per block. The program operations to the memory array can be done at the full page level or at the byte level (a variable number of bytes). Erase operations can be performed at the chip, block, or page level.

Figure 5-17. Device Block Memory Map — Block Erase Address Ranges

64 KB Block Erase (D8h)	32 KB Block Erase (52h)	4 KB Block Erase (20h) ⁽¹⁾	Block Address Range
64 KB (block 63)	32 KB (block 127)	4 KB (B1023)	3FF000h - 3FFFFFFh
		4 KB (B1022)	3FE000h - 3FEFFFh
		4 KB (B1021)	3FD000h - 3FDFFFh
		4 KB (B1020)	3FC000h - 3FCFFFh
		4 KB (B1019)	3FB000h - 3FBFFFh
		4 KB (B1018)	3FA000h - 3FAFFFh
		4 KB (B1017)	3F9000h - 3F9FFFh
		4 KB (B1016)	3F8000h - 3F8FFFh
	32 KB (block 126)	4 KB (B1015)	3F7000h - 3F7FFFh
		4 KB (B1014)	3F6000h - 3F6FFFh
		4 KB (B1013)	3F5000h - 3F5FFFh
		4 KB (B1012)	3F4000h - 3F4FFFh
		4 KB (B1011)	3F3000h - 3F3FFFh
		4 KB (B1010)	3F2000h - 3F2FFFh
		4 KB (B1009)	3F1000h - 3F1FFFh
		4 KB (B1008)	3F0000h - 3F0FFFh

1. B = Block

5.8 Memory Protection

The AT25XE321D device incorporates a robust memory protection scheme that allows memory locations to be protected down to the 4KB block level. The device provides the ability to globally lock all blocks in one operation, or to lock individual blocks on a per-block basis.

5.8.1 Standard Memory Protection

The standard memory protection scheme is invoked by clearing bit 2 (WPS) of Status register 3. When this bit is cleared, the AT25XE321D uses a combination of the following register fields to set the memory protection scheme:

- **CMPRT:** When this bit is set, unprotected areas of memory become protected, and protected areas of memory become unprotected. For example, when $CMPRT = 0$, a top 64 KB block can be protected while the rest of the array is not; when $CMPRT = 1$, the same 64 KB block would become unprotected while the rest of the array becomes read-only. Refer to bit 6 of [Section 6.4, Status Register 2](#) for more information.
- **BPSIZE:** This bit works in conjunction with bits 4:2 (BP[2:0]) in Status register 1 to determine the size of the blocks to be protected. Block sizes of 4 KB and 64 KB can be protected depending on the state of this bit. Refer to bit 6 of [Section 6.3, Status Register 1](#) for more information.
- **TB:** This bit indicates if the protection should be from the bottom up of the top down of the memory. Refer to bit 5 of [Section 6.3, Status Register 1](#) for more information.
- **BP[2:0]:** This field can be programmed to protect all of the memory array, none of the memory array, or a portion of the memory array. When that portion of the memory is protected, it is protected from the program and erase commands. Refer to bit 4:2 of [Section 6.3, Status Register 1](#) for more information.

The protection scheme differs based on the setting of the CMPRT bit described above. [Table 5-3](#) shows the relationship between the BPSIZE, BP[2:0], and TB bits when $CMPRT = 0$. The right-most column shows the protected address range. All addresses not shown are unprotected.

Table 5-3. AT25XE321D Device Block Protection Map — $CMPRT = 0$, $WPS = 0$

CMPRT	BPSIZE	TB	BP[2:0]	Protected Address Range
0	0	0	3'b000	NONE
0	0	0	3'b001	3F0000 - 3FFFFFF
0	0	0	3'b010	3E0000 - 3FFFFFF
0	0	0	3'b011	3C0000 - 3FFFFFF
0	0	0	3'b100	380000 - 3FFFFFF
0	0	0	3'b101	300000 - 3FFFFFF
0	0	0	3'b110	200000 - 3FFFFFF
0	0	0	3'b111	000000 - 3FFFFFF
0	0	1	3'b000	NONE
0	0	1	3'b001	000000 - 00FFFF
0	0	1	3'b010	000000 - 01FFFF
0	0	1	3'b011	000000 - 03FFFF
0	0	1	3'b100	000000 - 07FFFF
0	0	1	3'b101	000000 - 0FFFFFF
0	0	1	3'b110	000000 - 1FFFFFF

Table 5-3. AT25XE321D Device Block Protection Map — CMPRT = 0, WPS = 0 (continued)

CMPRT	BPSIZE	TB	BP[2:0]	Protected Address Range
0	0	1	3'b111	000000 - 3FFFFFF
0	1	0	3'b000	NONE
0	1	0	3'b001	3FF000 - 3FFFFFF
0	1	0	3'b010	3FE000 - 3FFFFFF
0	1	0	3'b011	3FC000 - 3FFFFFF
0	1	0	3'b100	3F8000 - 3FFFFFF
0	1	0	3'b101	3F8000 - 3FFFFFF
0	1	0	3'b110	000000 - 3FFFFFF
0	1	0	3'b111	000000 - 3FFFFFF
0	1	1	3'b000	NONE
0	1	1	3'b001	000000 - 000FFF
0	1	1	3'b010	000000 - 001FFF
0	1	1	3'b011	000000 - 003FFF
0	1	1	3'b100	000000 - 007FFF
0	1	1	3'b101	000000 - 007FFF
0	1	1	3'b110	000000 - 3FFFFFF
0	1	1	3'b111	000000 - 3FFFFFF

Table 5-4 shows the relationship between the BPSIZE, BP[2:0], and TB bits when CMPRT = 1.

Table 5-4. AT25XE321D Device Block Protection Map — CMPRT = 1, WPS = 0

CMPRT	BPSIZE	TB	BP[2:0]	Protected Address Range
1	0	0	3'b000	000000 - 3FFFFFF
1	0	0	3'b001	000000 - 3EFFFF
1	0	0	3'b010	000000 - 3DFFFF
1	0	0	3'b011	000000 - 3BFFFF
1	0	0	3'b100	000000 - 37FFFF
1	0	0	3'b101	000000 - 2FFFFFF
1	0	0	3'b110	000000 - 1FFFFFF
1	0	0	3'b111	NONE
1	0	1	3'b000	000000 - 3FFFFFF
1	0	1	3'b001	010000 - 3FFFFFF
1	0	1	3'b010	020000 - 3FFFFFF
1	0	1	3'b011	040000 - 3FFFFFF
1	0	1	3'b100	080000 - 3FFFFFF

Table 5-4. AT25XE321D Device Block Protection Map — CMPRT = 1, WPS = 0 (continued)

CMPRT	BPSIZE	TB	BP[2:0]	Protected Address Range
1	0	1	3'b101	100000 - 3FFFFFF
1	0	1	3'b110	200000 - 3FFFFFF
1	0	1	3'b111	NONE
1	1	0	3'b000	000000 - 3FFFFFF
1	1	0	3'b001	000000 - 3FEFFF ^{(1) (2)}
1	1	0	3'b010	000000 - 3FDFFF ^{(1) (2)}
1	1	0	3'b011	000000 - 3FBFFF ^{(1) (2)}
1	1	0	3'b100	000000 - 3F7FFF ⁽²⁾
1	1	0	3'b101	000000 - 3F7FFF ⁽²⁾
1	1	0	3'b110	NONE
1	1	0	3'b111	NONE
1	1	1	3'b000	000000 - 3FFFFFF
1	1	1	3'b001	001000 - 3FFFFFF ^{(3) (4)}
1	1	1	3'b010	002000 - 3FFFFFF ^{(3) (4)}
1	1	1	3'b011	004000 - 3FFFFFF ^{(3) (4)}
1	1	1	3'b100	008000 - 3FFFFFF ⁽⁴⁾
1	1	1	3'b101	008000 - 3FFFFFF ⁽⁴⁾
1	1	1	3'b110	NONE
1	1	1	3'b111	NONE

1. When the 32KB Erase command is used, the protected region is 0x00_0000 - 0x3F_7FFF.
2. When the 64KB Erase command is used, the protected region is 0x00_0000 - 0x3E_FFFF.
3. When the 32KB Erase command is used, the protected region is 0x00_8000 - 0x3F_FFFF.
4. When the 64KB Erase command is used, the protected region is 0x01_0000 - 0x3F_FFFF.

5.8.2 Individual Block Lock and Unlock

In addition to the standard protection scheme described in the previous subsection, the AT25XE321D device also provides the ability to lock individual memory locations. Protection of memory locations can be applied individually using the *Individual Block Lock* (36h) command and the *Individual Block Unlock* (39h) command. Note that in the AT25XE321D device all lock bits are set by default, making all memory locations protected. The user must execute a series of one or more *Individual Block Unlock* (39h) commands to unlock the desired memory locations.

The individual memory protection scheme is invoked by setting bit 2 (WPS) of status register 3. When this bit is set, the AT25XE321D uses the *Individual Block Lock* (36h) command that provides the address of the 4 KB or 64 KB block to be locked. Refer to [Table 6-6](#) for more information on the WPS bit.

[Figure 5-17](#) above shows the address ranges for each 4 KB block corresponding to the top and bottom 64 KB blocks of the memory map. The appropriate 24-bit address is driven on the SI pin after the 36h command. After decoding the command, hardware reads the address and sets the appropriate lock bit for that 4 KB block.

Note that the ability to lock 4 KB blocks only applies to the top and bottom 64 KB blocks of the map. This corresponds to blocks 0 and 63. For 64 KB blocks 1 - 62, the blocks can only be locked on the 64 KB boundary (1 lock bit per 64 KB). This equates to a total of 94 lock bits;

- 16 bits, one per 4 KB sub-block in the top 64 KB block
- 16 bits, one per 4 KB sub-block in the bottom 64 KB block
- 62 bits, one each for 64 KB blocks 1 - 62

Refer to [Section 7.21, Individual Block Lock \(36h\)](#) and [Section 7.22, Individual Block Unlock \(39h\)](#) for more information.

5.8.3 Global Block Lock and Unlock

In addition to individual block protection of memory locations as described in the previous subsection, the AT25XE321D also allows for the blocks to be locked and unlocked globally using the *Global Block Lock* (7Eh) and the *Global Block Unlock* (98h) commands. Note that in the AT25XE321D device all lock bits are set by default, making all memory locations protected. The user must execute a *Global Unlock Block* command to unlock the memory locations.

Refer to [Section 7.24, Global Block Lock \(7Eh\)](#) and [Section 7.25, Global Block Unlock \(98h\)](#) for more information.

5.8.4 Reading the State of the Lock Bits

In addition to globally or individually locking and unlocking selected memory blocks as described above, the AT25XE321D device allows the user to poll any block in memory to determine if it has been locked. This is accomplished by executing either the 3Ch or 3Dh command, along with the 24-bit address. Both of these command perform the exact same operation and can be used interchangeably.

Once this information is decoded, hardware fetches the 8-bit lock field from the requested location and outputs this information onto the SO pin. The most significant bit (MSB) of the value is transferred first, and the least significant bit (LSB) is transferred last. If the LSB is 1, the corresponding block is locked and no erase or program operation can be executed to that block. If the LSB is 0, the block or section is unlocked and program/erase operations are allowed. Refer to [Section 7.23, Read Block Lock \(3Ch/3Dh\)](#) for more information.

5.9 Power Down Considerations

The AT25XE321D device supports the *Deep Power Down* (B9h) and *Ultra Deep Power Down* (79h/B9h) modes. In addition, bit 7 (PDM) of Status register 4 (SR4) can be used to select either of these modes using the B9h command. The 79h command is provided for backward compatibility.

There are three ways to enter power down mode:

1. Set the PDM bit in SR4 (logic 1) and execute the B9h command to place the device into *Deep Power Down* (DPD) mode. In this mode it is possible to execute the *Resume from Deep Power Down* (ABh) command or *Enable Reset* (66h) and *Reset Device* (99h) commands in order to exit DPD mode. The content of SRAM buffer is preserved in this case. The device could also be reset by JEDEC reset, hardware reset, or power-on-reset in order to exit DPD mode. The exit from DPD mode time is defined by the t_{RDPD} timing parameter in the AC specifications section of this document. Refer to [Section 5.9.2](#) below. Note that in the AT25XE321D device, simply deasserting \overline{CS} as in other devices does not exit DPD mode.
2. Clear the PDM bit in SR4 (logic 0) and execute the B9h command to place the device into *Ultra-Deep Power Down* (UDPD) mode. To exit this mode, it is necessary to execute the *Resume from Ultra-Deep Power Down* (ABh) command or a JEDEC reset, hardware reset, or power-on-reset to initiate an internal reset of the device. The contents of the SRAM buffer are NOT preserved. The resume from UDPD mode recovery time is defined by the t_{RUDPD} timing parameter in the AC specifications section of this document. Refer to [Section 5.9.2](#) below. Note that in the AT25XE321D device, simply deasserting \overline{CS} as in other devices does NOT exit UDPD mode.

- Execute the 79h command to place the device into Ultra-Deep Power Down (UDPD) mode. If this command is used, the state of the PDM bit in SR4 is ignored. This mode allows for software backward compatibility. A device reset is required to exit UPDP mode. In this mode it is necessary to execute the *Resume from Ultra-Deep Power Down* (ABh) command or a JEDEC reset, hardware reset or power-on-reset to initiate an internal reset of the device. The contents of the SRAM buffer are NOT preserved. The exit from UDPD mode recovery time is defined by the t_{RUDPD} timing parameter in the AC specifications section of this document. Refer to [Section 5.9.2](#) below for more information on exiting power down mode.

5.9.1 Entering Power Down Mode

The conditions for entering DPD or UDPD mode are shown in the [Table 5-5](#). The PDM column indicates the state of the Power Down Mode bit in Status Register 4.

Table 5-5. Entering DPD or UDPD Mode

Command	PDM bit	Power Down Mode	SRAM Contents	Power Down Exit Recovery Time
B9h	1	Deep Power Down	Retained	Short
B9h	0	Ultra Deep Power Down	Lost	Long
79h	x	Ultra Deep Power Down	Lost	Long

5.9.2 Exiting Power Down Mode

The following methods can be used to exit DPD or UDPD mode.

Table 5-6. Exiting DPD or UDPD Mode

Command	PDM bit	Power Down Mode	Exit Command	Power On Reset	JEDEC Reset	Hardware Reset Pin ⁽¹⁾	66h/99h Command	Terminate (F0h)	Status After Exit
B9h	1	DPD	ABh ⁽²⁾	Y	Y	Y	Y	N	Idle
B9h	0	UDPD	ABh ⁽³⁾	Y	Y	Y	N	N	Idle
79h	x	UDPD	ABh ⁽³⁾	Y	Y	Y	N	N	Idle

1. Hardware reset function must be enabled by software before entering the Power Down mode. See bit 7 of Status Register 3.

2. Executing the ABh command in DPD mode returns the device to an idle state. The SRAM contents are retained.

3. Executing the ABh command in UDPD mode causes the device to initiate an internal reset sequence. The SRAM contents are undefined.

ABh Command

Executing the ABh command while in the Deep Power Down (DPD) mode causes the device to exit DPD and return back to an idle state. This command does not reset the device and no data is lost. Executing the ABh command while in the Ultra-Deep Power Down (UDPD) mode causes the device to perform an internal reset. In this case the SRAM contents are undefined.

Device Resets

In addition to the ABh command described above, performing a Power On Reset (POR), a JEDEC reset, or asserting the hardware reset pin ($\overline{\text{RESET}}$) also causes the device to exit DPD or UDPD mode. If the device is reset in any of these three ways, the SRAM contents are undefined.

Enable Reset (66h) / Reset (99h) Command

As shown in [Table 5-6](#), the 66h/99h reset command is accepted in DPD mode. In this case the SRAM contents are retained. The device will not exit UDPD mode, regardless of whether the device entered UDPD mode using the B9h command or the 79h command. To exit UDPD mode, the device must be reset as described in the previous subsections.

Terminate Command (F0h)

The *Terminate* (F0) command does not cause exit from DPD or UDPD modes. To exit DPD or UDPD mode still requires either the ABh command, or resetting the device as described in the previous subsections.

5.9.3 Reset During Program and Erase Commands

The AT25XE321D device supports the following program and erase operations.

Program operations include:

- Byte/Page Program (02h)
- Sequential Program (AFh/ADh)
- Dual Output Byte/Page Program (A2h)
- Quad Output Byte/Page Program (32h)
- Read-Modify-Write (0Ah)
- Main Memory Page Program Without Erase (88h)
- Program Security Register (9Bh)

Erase operations include:

- Page Erase (81h/DBh)
- 4KB Block Erase (20h)
- 32KB Block Erase (52h)
- 64KB Block Erase (D8h)
- Chip Erase (60h/C7h)

These commands are affected when resetting the device as shown in [Table 5-7](#). In this table, a ‘Y’ entry indicates that the device is reset when that type of reset occurs during the corresponding command. A ‘N’ entry indicates that the operation is stopped, but the device is not reset. For example, when the F0h command is executed during a program or erase operation, the operation is halted, but the device is not reset.

Table 5-7. Resetting the Device During a Program or Erase Operation

Command Type	Power On Reset	JEDEC Reset	Hardware Reset Pin	66h/99h Command	Terminate (F0h)
Program	Y	Y	Y	Y	N
Erase	Y	Y	Y	Y	N

5.10 Erase/Program Suspend Considerations and Nested Operations

The AT25XE321D device provides three status register bits to manage program and erase suspend operations.

- SUSP — Status Register 2, bit 7. The SUSP bit is set by hardware and indicates that the program or erase operation has been suspended.
- ES — Status Register 5, bit 3. The ES bit is set by hardware whenever an erase operation is suspended.
- PS — Status Register 5, bit 2. The PS bit is set by hardware whenever a program operation is suspended.

These three bits work in conjunction to define the state of a suspend operation as shown in [Table 5-8](#).

In this table, the SUSP is a logical OR of the ES and PS bits. When either the ES or PS bit is set, the SUSP bit is set. When both of the ES and PS bits are cleared, the SUSP bit is cleared.

These bits relate to the flow diagram in [Figure 5-19](#) below as follows: when the erase operation is suspended, hardware sets the ES bit. When the program operation is suspended, hardware sets the PS bit. Once the program operation is complete, hardware clears the PS bit. Finally, when the erase operation is completed, hardware clears the ES bit.

Table 5-8. Encoding of Erase/Program Suspend Operations

SUSP	ES	PS	Status
0	0	0	No suspend operation in progress.
1	0	1	Program suspend operation in progress.
1	1	0	Erase suspend operation in progress.
1	1	1	Nested erase/program suspend operation in progress.

5.10.1 Nested Operations

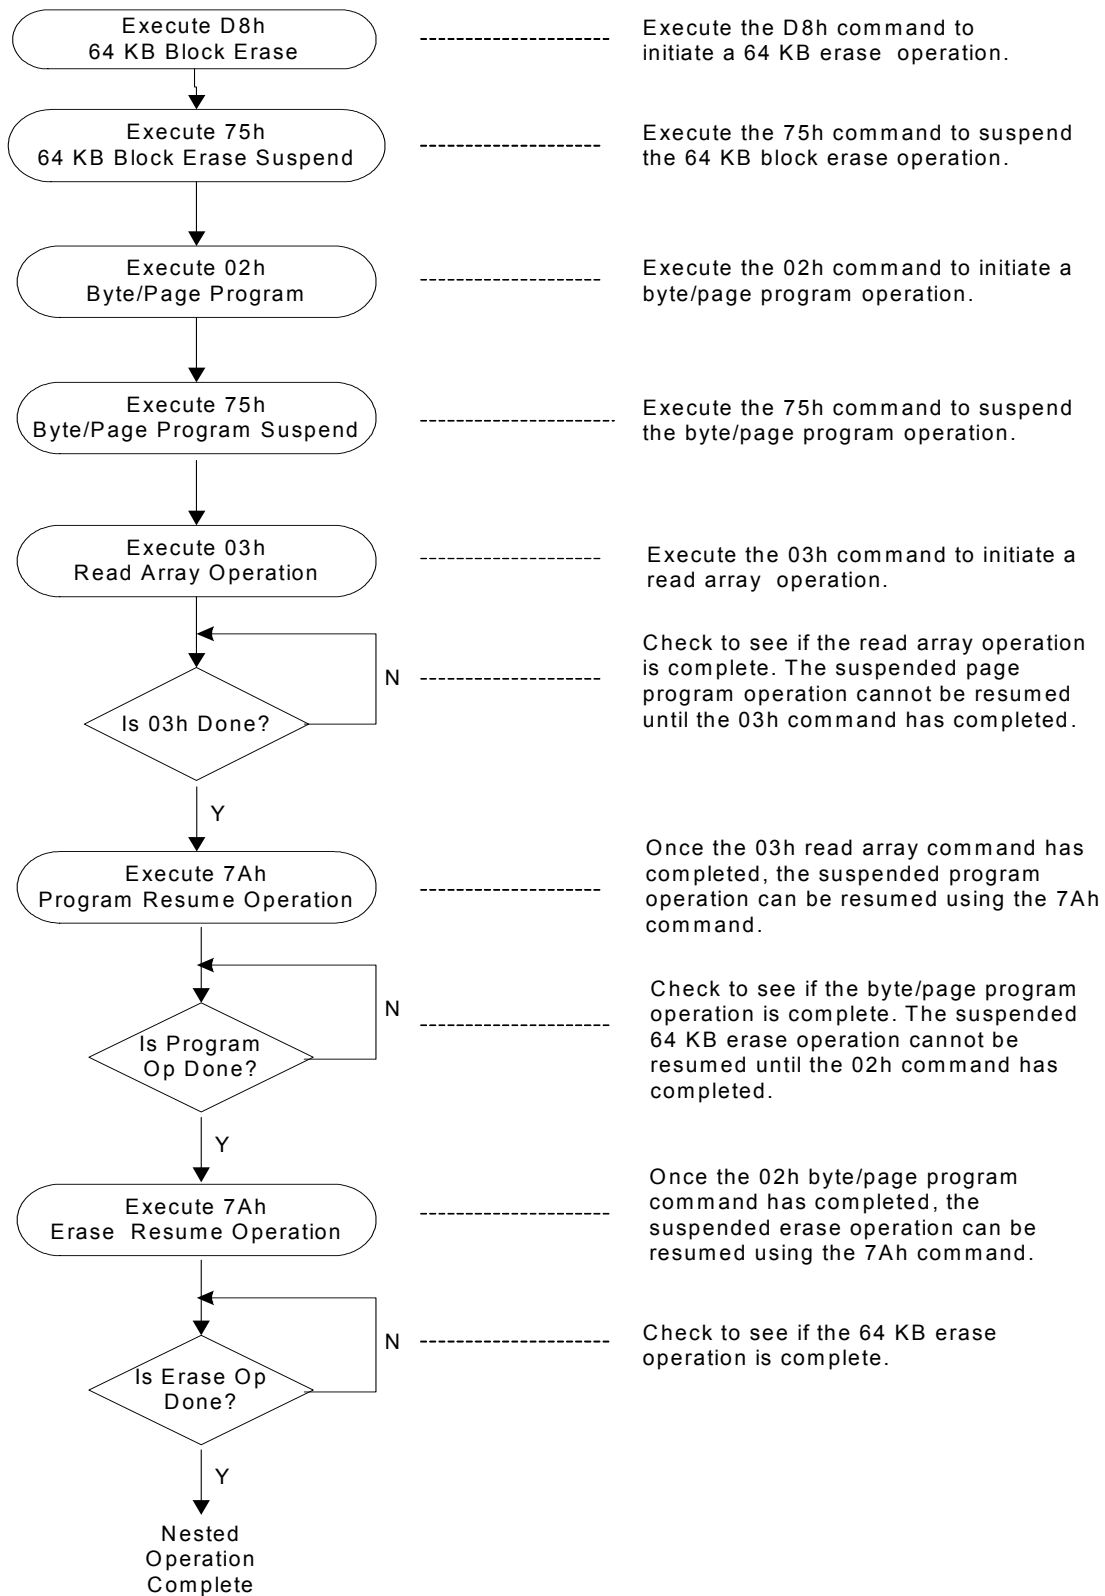

The AT25XE321D device supports nested erase and program suspend operations. An erase operation can be suspended and a program operation started. This operation can then also be suspended and another operation commenced, such as a read. After the read operation is complete, the program operation can be resumed. Once the program operation is completed, the erase operation can be resumed. Nested operations adhere to the following constraints:

- Suspending an erase operation followed by a program operation is supported
- Suspending a program operation followed by an erase operation is NOT supported

The erase operation must be suspended first, followed by suspension of the program operation.

[Figure 5-19](#) shows a flow diagram of a nested operation example.

Figure 5-19. Flow Diagram of Nested Operations Example

5.10.2 Suspending and Terminating a Program or Erase Operation

Program Operation

A self-timed program operation can be suspended using the *Suspend* (75h) command and terminated using the *Terminate* (F0h) command. The device responds to either of these commands by initiating a sequence which completes some internal sub-operations, brings the internal voltage supplies to their quiescent state, saves the intermediate address counters and states, and sets the PS (Program Suspend) bit in Status register 4 in the case of a *Suspend* command.

When the user issues the *Suspend* command the device requires a period of time equal to t_{SUS} before the BUSY flag goes low and the PS flag goes high.

Erase Operation

A self-timed erase operation can be suspended using the *Suspend* (75h) command and terminated using the *Terminate* (F0h) command. The device responds to either of these commands by initiating a sequence which completes some internal sub-operations, brings the internal voltage supplies to their quiescent state, saves the intermediate address counters and states, and sets the ES (Erase Suspend) bit in status register 4 in the case of a *Suspend* command.

Terminate After Suspend

If the time between the *Suspend* command and the *Terminate* command is large enough, then the device may finish the internal suspend operation before the *Terminate* command is received. In this case, the device clears the BUSY bit in Status register 1, and the ES/PS flags in Status register 5 are set. Now when the device receives the *Terminate* command, it is ignored by the hardware. This concept is shown in [Figure 5-20](#).

Figure 5-20. Allowing Enough Time for the Suspend Operation to Complete

If the user wishes to perform another program/erase operation, they must check the ES or PS flag in Status register 4 to determine if the operation can proceed.

If the ES/PS bit is cleared, the user can issue a new *Program/Erase* command. Note that previous *Program/Erase* command that was terminated leaves that region of memory in an intermediate state, and it is recommended to erase this region of memory before attempting to reprogram it.

If the ES/PS bit is set, then the user cannot issue another *Program/Erase* command. The user must first issue a *Resume* command to re-start the suspended program/erase operation, then either allow it to run to completion or terminate it using the *Terminate* command. The user can now issue a new *Program/Erase* command.

5.10.3 Terminating a Non-Volatile Register Operation in Progress

The *Terminate* (F0h) command, the *Software Reset* command (66h + 99h), the hardware reset (\overline{RESET} on IO₃) pin, and the JEDEC Reset are ways to stop any on-going internal self-timed program/erase operation (and in some cases reset the device). However, abruptly terminating the *Status Register Write*, *Status Register Lock*, or *OTP Security Register Program* command is not desirable as this may leave these non-volatile registers in an indeterminate state.

Therefore when the device is busy executing the *Status Register Write*, the *Status Register Lock* or the *OTP Security Register Program* command, then the *Terminate* command is ignored. The software reset, hardware reset, and JEDEC reset actions are delayed until after the internal self-timed operations are completed; once the internal operation is completed the device will be reset. Refer to [Section 5.12](#) for more information on how to perform a JEDEC hardware reset.

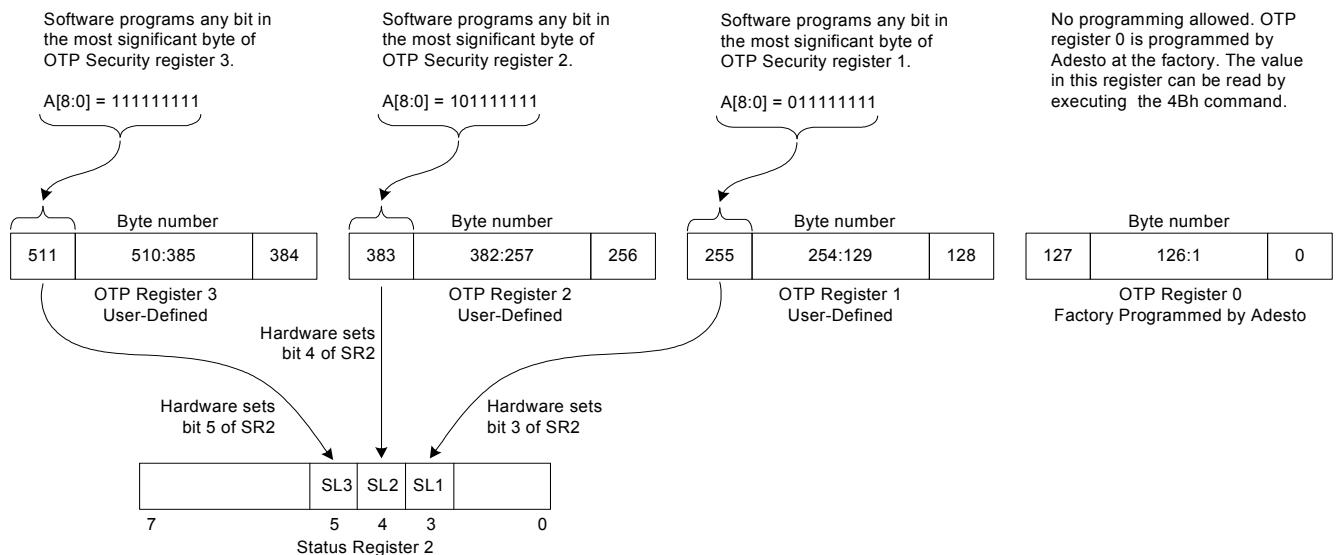

5.11 OTP Security Register Lock

The AT25XE321D device supports four 128-byte OTP security registers. One register is programmed by Adesto at the factory and is always locked. The other three OTP registers can be programmed by the user and become locked whenever any bit in the most significant byte of that register is written. In response to this write operation, hardware writes bits 5:3 (SL3:SL1) of Status register 2 to indicate that the corresponding register has been locked. Software can read this field to determine which registers have been locked.

Each byte of each register can be written using address bits 8:0 that are driven with the Program OTP Security register command (9Bh). Refer to [Table 7-19](#) in [Section 7.26, Program Security Register \(9Bh\)](#) for an exact encoding of these address bits.

This concept is shown in [Figure 5-21](#). In this figure, A[8:7] are used to select between the four OTP Security registers, and A[6:0] are used to select one of the 128 bytes within that register. A value of 7'b11111111 on A[6:0] indicates an access to the MSB of that register as shown below.

Figure 5-21. OTP Security Register Program and Lock

5.12 Standard JEDEC Hardware Reset

The JEDEC hardware reset sequence does not use the SCK pin. The SCK pin must be held low (mode 0) or high (mode 3) through the entire reset sequence. This prevents any confusion with a command, as no command bits are transferred.

A reset is commanded when the data on the SI pin is 0101 on four consecutive positive edges of the $\overline{\text{CS}}$ pin with no edge on the SCK pin throughout. This is a sequence where

1. $\overline{\text{CS}}$ is driven active low to select the device
2. Clock (SCK) remains stable in either a high or low state
3. SI is driven low by the bus master, simultaneously with $\overline{\text{CS}}$ going active low. No SPI bus slave drives SI during $\overline{\text{CS}}$ low before a transition of SCK

4. $\overline{\text{CS}}$ is driven inactive. The slave captures the state of SI on the rising edge of $\overline{\text{CS}}$

The above steps are repeated 4 times, each time alternating the state of SI.

After the fourth $\overline{\text{CS}}$ pulse, the slave triggers its internal reset. SI is low on the first CS, high on the second, low on the third, high on the fourth. This provides a value of 5h, unlike random noise. Any activity on SCK during this time halts the sequence and a Reset will not be generated.

After a JEDEC hardware reset while the device is in Ultra-Deep Power Down (UDPD) mode, the SRAM buffer resets to an undefined value. Hardware resets all volatile status registers, including the block protection bits, to their default values.

After a JEDEC hardware reset while the device is in any other mode than UDPD mode, the SRAM buffer keeps the values it had prior to Reset, with the following exception: If the reset sequence is initiated during an update of the SRAM buffer, the contents of the SRAM buffer may be corrupted. Hardware resets all volatile status registers, including the block protection bits, reset to their default values.

All non-volatile status registers keep the value they had prior to reset, with the following exception: If the reset sequence is initiated during a write to a non-volatile status register, the value of that register may be corrupted.

The device will always revert back to standard SPI mode after JEDEC hardware reset. [Figure 5-22](#) below illustrates the timing for the JEDEC hardware reset operation.

Figure 5-22. JEDEC Standard Hardware Reset

5.13 Chip Select Restrictions

The $\overline{\text{CS}}$ pin is used to start and end operations in the device. Once the $\overline{\text{CS}}$ pin is asserted and the operation begins, it can only be deasserted on a byte boundary. If the $\overline{\text{CS}}$ pin is deasserted on a non-byte boundary, the operation is ignored.

For example, when executing the ABh command to exit power down mode, only the command is required. No address and data are required to perform this operation. Therefore, only eight clocks are required to transfer the command. If the $\overline{\text{CS}}$ pin is raised after the 8th clock (most significant bit of the command is transferred), hardware performs the operation. If the $\overline{\text{CS}}$ pin is raised after the 9th or 10th clock (not a byte boundary), the operation is ignored and no ABh command is executed.

Similarly, if the ABh command is used to fetch the device ID, once the $\overline{\text{CS}}$ pin is asserted, 40 clock cycles are required: 8 clocks for the command, 24 dummy clocks, and 8 clocks to shift out the device ID. If the $\overline{\text{CS}}$ pin is raised after the 40th clock, hardware transfers the ID information, exits power down mode, and completes the operation. However, if the $\overline{\text{CS}}$ pin is raised on the 41st or 42nd clock (not a byte boundary), the ID information is still returned as that occurred in clocks 32 - 40, but the device will not exit power down mode.

5.14 Active Status Interrupt

When a program or erase operation is in progress, there are two ways to determine when the operation has finished.

- Repeatedly poll bit 0 ($\overline{\text{RDY}}/\text{BSY}$) of Status register 1 looking for a high to low transition
- Once the program or erase operation begins, execute the *Active Status Interrupt* (25h) command and watch for a high to low transition on the SO pin

For example, assume a *Byte/Page Program* (02h) operation is initiated and 256 bytes are transferred into the buffer. Once the CS pin is deasserted, indicating the completion of the 02h command, hardware sets the $\overline{\text{RDY}}/\text{BSY}$ bit and starts moving the data to memory. Executing the 25h command causes hardware to drive the state of the $\overline{\text{RDY}}/\text{BSY}$ bit onto the SO pin. This allows external logic to monitor the state of the SO pin for a high to low transition.

When the *Active Status Interrupt* (25h) command is used, the SO pin can be connected to an external interrupt controller. The controller recognizes the high to low transition and takes the appropriate action. This command is an alternative to the polling of the $\overline{\text{RDY}}/\text{BSY}$ bit in Status register 1 and uses less overhead than continually executing the 05h command to read the contents of Status register 1.

5.15 Low Battery Detect

The AT25XE321D device includes a *Low Battery Detect* (EFh) command that can be used to probe the battery and determine its status. The low battery detect function is programmable. Software uses Status register (SR6) to program parameters such as what voltage level constitutes a low battery, and how much load is applied to the battery to determine the amount of charge left. Another field sets the amount of time the desired load is applied to the battery.

Status register 6 is used in the following manner to determine the low battery status. For the exact programmable values for these registers fields, refer to [Section 6.4, Status Register 2](#).

1. Program the LBVL field (bits 5:3) of SR6 to set the low battery detect level. When a test is performed, the device will not indicate a low voltage level until that level falls below the value programmed into this field. Values range from 1.8V to 3.2V in 200 mV increments.
2. Program the LBLD field (bits 2:1) of SR6 to indicate the amount of load applied to the battery for testing purposes. The amount of load applied ranges from 0 μA to 10 mA.
3. Program the LBD field (bit 0) to indicate the amount of delay from the battery load test. Values of 100 μs and 1 ms are supported.
4. Execute the *Low Battery Detect* (EFh) command. This operation sets bits 7:6 (LBST) of SR6 to a value of 2'b01, indicating that a low battery detect operation is in progress.
5. Once the operation is complete, software can poll bits 7:6 of SR6 to determine the result of the test. If this field contains a value of 2'b10, the voltage in the battery is greater than the threshold set by the LBVL field. A value of 2'b11 indicates the voltage in the battery is less than the threshold set by the LBVL field. Alternatively, the active status interrupt (25h) command can be used to determine when the test has completed. Refer to the previous subsection for more information on the active status interrupt command.

Refer to [Section 7.43, Low Battery Detect \(EFh\)](#) for more information.

5.16 Read-Modify-Write

The AT25XE321D device incorporates a completely self-contained Read-Modify-Write (R-M-W) operation (command 0Ah) that can be used to reprogram any number of sequential bytes in a page in the main memory array without affecting the rest of the bytes in the same page. This command allows the device to easily emulate an EEPROM by providing a method to modify a single byte or more in the main memory in a single operation, without the need for pre-erasing the memory or the need for any external RAM buffers. The main advantage of this command is that it allows a memory location to be erased and reprogrammed in one operation.

Refer to [Section 7.41, Byte Write \(Read-Modify-Write\) \(0Ah\)](#) for more information on the 0Ah command.

5.17 **HOLD / RESET Function**

The AT25XE321D device provides a configurable $\overline{\text{HOLD/RESET}}$ pin. This pin can be configured to operate as either a $\overline{\text{HOLD}}$ pin, or as a device $\overline{\text{RESET}}$ pin, by programming bit 7 (HOLD/RESET) of Status register 3. When this bit is cleared, the $\overline{\text{HOLD/RESET}}$ pin functions as an active low $\overline{\text{HOLD}}$ pin. When this bit is set, the $\overline{\text{HOLD/RESET}}$ pin functions as a active low device $\overline{\text{RESET}}$ pin.

The HOLD/RESET function is only valid in the SPI and dual modes of operation. When bit 1 (QE) of Status register 2 is set, indicating the device is in one of the quad modes (quad output or I/O) the HOLD/RESET functions are not available and the pin functions as the I/O_3 data pin.

When configured as a $\overline{\text{RESET}}$ pin, no commands will be accepted while the pin is low and the device is in reset.

Configuring the pin for the HOLD function allows an operation to be paused, then resumed when the $\overline{\text{HOLD}}$ pin is deasserted. Once the $\overline{\text{HOLD}}$ pin is asserted (with $\overline{\text{CS}}$ low), the HOLD function takes effect on the next falling edge of SCK. Conversely, once the $\overline{\text{HOLD}}$ pin is deasserted, the HOLD function is removed on the next falling edge of SCK. Note that the $\overline{\text{CS}}$ pin must be low for the entire time in which the HOLD operation is in progress.

The HOLD function can be used in situations where the clock and data signals of the AT25XE321D device are shared with other external agents, allowing the device to share the bus with other high priority events such as interrupts or other events that need immediate attention. Once the condition is resolved, the $\overline{\text{HOLD}}$ pin can be deasserted, allowing the operation to resume.

During the time the $\overline{\text{HOLD}}$ pin is asserted, the Serial Output (SO) pin is forced to the high impedance state. The state of the Serial Input (SI) and Serial Clock (SCK) pins are ignored. Note that the $\overline{\text{CS}}$ pin must be low for the entire time in which the HOLD operation is in progress.

6. Status Registers

The device contains six Status registers (SR) described in the following subsections. The Status registers can be read to determine the device's ready/busy status, as well as the status of many other functions such as hardware locking and software protection.

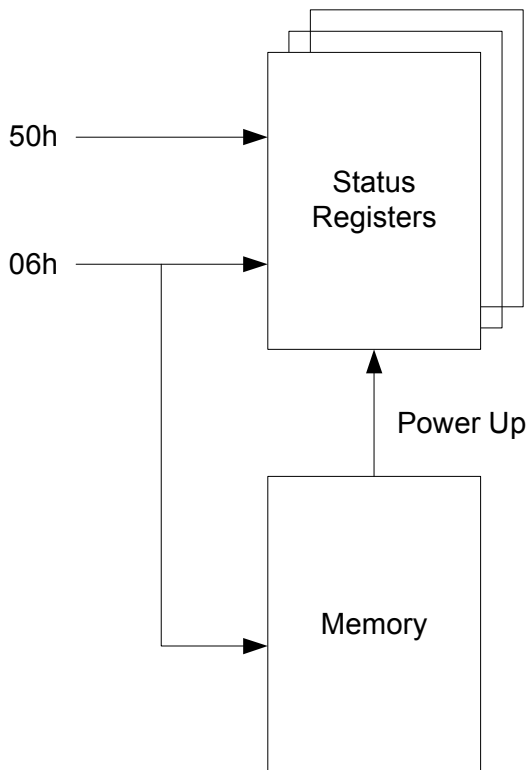

6.1 Register Structure and Updates

In the AT25XE321D device there are two sets of Status registers. One set is implemented in hardware and is accessed as Status registers 1 - 6. These are known as volatile registers as their data is lost during a device reset. In addition, the device keeps a copy of the Status registers in memory. These are known as non-volatile registers because they are stored in the Flash and are not affected by a device reset. On power up, the non-volatile contents of the memory are copied to the Status registers. Refer to [Section 6.2.2](#) for more information on volatile and non-volatile register types.

The AT25XE321D provides two methods for updating the Status Registers. When the *Write to Status Register* command is preceded by the *Volatile Status Register Write Enable* (50h) command, only the flip-flops holding the Status register bits are updated; the non-volatile memory dedicated to the Status registers is not updated. When the *Write to Status Register* command is preceded with a *Write Enable* (06h) command, then both the flip-flops holding the Status register bits and the non-volatile memory dedicated to the Status registers are updated. This concept is shown in [Figure 6-1](#).

The main difference between these two commands is the time required to execute them. Accesses to memory are much slower by default. So for the 50h command, the write is to the volatile Status registers only which is very fast. For the 06h command, the write is to non-volatile memory which is much slower.

Figure 6-1. AT25XE321D Register Structure

6.2 Register Accesses

This section describes the various ways to access the AT25XE321D Status registers. The AT25XE321D incorporates six Status registers. Each of these registers can be written or read using both the direct and indirect addressing methods as described in [Section 6.2.1](#). In addition, the device supports both volatile and non-volatile registers as described in [Section 6.2.2](#).

6.2.1 Direct and Indirect Addressing

The AT25XE321D device supports both direct and indirect addressing for accessing the Status registers. The indirect addressing method can be used for all six Status registers, and the direct addressing for the first three Status registers. This means that Status registers 4 - 6 can only be accessed using the indirect addressing method.

Historically, Adesto products have supported at most three Status registers. These registers have been accessed using the direct addressing method, where every register has a specific command used to access it and perform read or write operations. An example of these commands is as follows:

- 05h: Read Status Register 1
- 35h: Read Status Register 2
- 15h: Read Status Register 3
- 01h: Write Status Register 1
- 31h: Write Status Register 2
- 11h: Write Status Register 3

The above commands have been retained to provide backward compatibility with existing software. In addition to the direct method, the AT25XE321D device also provides an indirect method. In the indirect method, a single command (65h) is used to execute a read operation on all of the Status registers. Another command (71h) is used to execute a write operation on all of the Status registers. Once the command is provided, an 8-bit address field is used to determine which register to access. The encoding of the address field is shown in [Table 6-1](#).

Table 6-1. Indirect Addressing of Status Registers

Command	Address	Action
65h	01h	Read Status Register 1
	02h	Read Status Register 2
	03h	Read Status Register 3
	04h	Read Status Register 4
	05h	Read Status Register 5
	06h	Read Status Register 6
71h	01h	Write Status Register 1
	02h	Write Status Register 2
	03h	Write Status Register 3
	04h	Write Status Register 4
	05h	Write Status Register 5
	06h	Write Status Register 6

Note that by using the indirect address method, an address width of 8 bits indicates that up to 256 registers can be accessed, allowing for future expansion without requiring additional commands or associated hardware complexity.

6.2.2 Volatile and Non-Volatile Register Accesses

As shown in [Figure 6-1](#), the AT25XE321D device supports both volatile and non-volatile register accesses. Volatile register accesses are to the Status registers implemented in hardware. Non-volatile register accesses are to the Status registers stored in memory. During power-up, the contents of the registers in memory are copied to the hardware Status registers.

As shown in [Figure 6-1](#), the 50h command writes only to the volatile register set, whereas the 06h command writes to both the volatile and non-volatile register sets.

6.3 Status Register 1

The following table shows the bit assignments for Status register 1.

Table 6-2. Status Register 1 Format

Bit #	Acronym	Name	Type	Default	Description
7	SRP0	Status Register Protect 0	R/W	0	The SRP0 bit works in conjunction with the SRP1 bit in Status Register 1 and the WP pin to control write protection. Types of protection include software protection, hardware protection, one-time programmable (OTP) protection, and power supply lock-down protection. Refer to Table 6-4 for an encoding of these bits.
6	BPSIZE	Block Protect Size	R/W	0	The BPSIZE bit controls the size of the blocks protected by the Block Protect Bits (BP2, BP1, BP0 in bits 4:2 of this register). This bit is encoded as follows: 0: 64 KB block size 1: 4 KB block size The blocks can also be protected from the bottom up or from the top down as described in the TB bit of this register.
5	TB	Top/Bottom	R/W	0	The TB bit controls the direction of the blocks to be protected by the Block Protect Bits (BP2, BP1, BP0 in bits 4:2 of this register). This bit is encoded as follows: 0: Protect from bottom up 1: Protect from top down The size of the protected blocks can also be selected as described in the BPSIZE bit of this register.
4:2	BP2:0	Block Protect	R/W	000	The 3-bit Block Protect field provides write protection control and status. These bits are set using the Write Status register 1 (01h) command. This field can be programmed to protect all of the memory array, none of the memory array, or a portion of the memory array. When that portion of the memory is selected, it is protected from the Program and Erase commands as described in the Memory Protection table. The default is 3'b000 for this field, indicating that none of the memory array is protected.

Table 6-2. Status Register 1 Format (continued)

Bit #	Acronym	Name	Type	Default	Description
1	WEL	Write Enable Latch Status	R	0	<p>The WEL bit indicates the current status of the internal Write Enable Latch. When the WEL bit is in the logic “0” state, the device does not accept any program, erase, memory protection, or Write Status Register commands. The WEL bit defaults to the logic “0” state after a device power-up or reset.</p> <p>This bit is encoded as follows: 0: Device is not write enabled (default). 1: Device is write enabled.</p> <p>If the WEL bit is in the logic “1” state, it will not be reset to a logic “0” if an operation aborts due to an incomplete or unrecognized command being clocked into the device before the CS pin is deasserted.</p> <p>In order for the WEL bit to be reset when an operation aborts prematurely, the entire command for a program, erase, memory protection, or Write Status Register command must have been clocked into the device.</p> <p>When the Write Enable (06h) command is executed, the WEL bit is set. Conversely, when the Volatile Status Register Write Enable (50h) command is executed, the WEL bit is not set.</p>
0	$\overline{\text{RDY}}/\text{BSY}$	Ready/Busy Status	R	0	<p>The $\overline{\text{RDY}}/\text{BSY}$ bit is used to determine whether or not an internal operation, such as a program or erase, is in progress. To poll the $\overline{\text{RDY}}/\text{BSY}$ bit to detect the completion of a program or erase cycle, new Status Register data must be continually clocked out of the device until the state of the $\overline{\text{RDY}}/\text{BSY}$ bit changes from a logic “1” to a logic “0”.</p> <p>This bit is encoded as follows: 0: Device is ready. 1: Device is busy with an internal operation.</p>

6.4 Status Register 2

The following table shows the bit assignments for Status register 2.

Table 6-3. Status Register 2 Format

Bit #	Acronym	Name	Type	Default	Description
7	SUSP	Suspend Status	R	0	<p>The SUSP bit is set by hardware and indicates that the program or erase operation has been suspended. This bit is set after software executes an Erase/Program Suspend (75h) command. Hardware clears this bit when it detects that any of the following conditions have occurred:</p> <ul style="list-style-type: none"> Erase/Program Resume (7Ah) command Hardware Reset, JEDEC Hardware Reset 66h / 99h Reset command

Table 6-3. Status Register 2 Format (continued)

Bit #	Acronym	Name	Type	Default	Description
6	CMPRT	Complement Protect	R/W	0	<p>The CMPRT is used in conjunction with BPSIZE, TB, and BP2:BP0 bits to provide additional memory array protection. This bit is encoded as follows:</p> <p>0: Current protection mechanism is unchanged 1: Current protection mechanism is reversed</p> <p>When this bit is set, unprotected areas of memory become protected, and protected areas of memory become unprotected. For example, when CMPRT = 0, a top 64 KB block can be protected while the rest of the array is not; when CMP = 1, the same 64 KB block would become unprotected while the rest of the array becomes read-only.</p>
5:3	SL3:SL1	Security Lock 3:1	R	000	<p>The 3-bit SL3:SL1 field provides One-Time-Program (OTP) lock status of Security registers 1 - 3. This field is used by software to determine which of these Security registers have been locked. Note that Security register 0 is always locked as the value is programmed by Adesto at the factory.</p> <p>The default state of SL[3:1] is 0, indicating that all registers are unlocked. Each bit corresponds to a Status register as follows:</p> <p>SL3 (bit 5): Security register 3 SL2 (bit 4): Security register 2 SL1 (bit 3): Security register 1</p> <p>Each bit in this field is set by hardware when the most significant byte of the corresponding Security register (the 128th byte) is programmed.</p> <p>For example, when the MSB of Security register 1 is set, bit 3 (SL1) of this field is set. Conversely, when the MSB of Security register 3 is set, bit 5 (SL3) of this field is set. Each time a bit is set, it indicates that the corresponding 128-Byte Security register has become read-only permanently.</p>
2	R	Reserved	R	0	Reserved
1	QE	Quad Enable	R/W	0	<p>The QE bit enables Quad SPI and XiP operation. This bit is encoded as follows:</p> <p>0: QE mode is disabled 1: QE mode is enabled</p> <p>When the QE bit is cleared (logic 0), the \overline{WP} and $\overline{HOLD} / \overline{RESET}$ pins are enabled and perform their respective functions.</p> <p>When the QE bit is set (logic 1), the \overline{WP} and $\overline{HOLD} / \overline{RESET}$ pins function as the IO₂ and IO₃ pins respectively, and the \overline{WP} and $\overline{HOLD} / \overline{RESET}$ pins functions are disabled.</p> <p>This bit only pertains to the following commands:</p> <p>6Bh: Quad Output Read EBh: XiP Mode Read E7h: Quad I/O Read with Double-word Aligned Address 32h: Quad Output Program 77h: Set Burst with Wrap 94h: Quad I/O Manufacturer/Device ID</p>

Table 6-3. Status Register 2 Format (continued)

Bit #	Acronym	Name	Type	Default	Description
0	SRP1	Status Register Protect 1	R/W	0	The SRP1 bit works in conjunction with the SRP0 bit in Status Register 0 and the \overline{WP} pin to control write protection. Types of protection include software protection, hardware protection, one-time programmable (OTP) protection, and reset lock-down protection. Refer to Table 6-4 for an encoding of these bits.

[Table 6-4](#) shows the operation of the SRP[1:0] volatile Status register bits during normal operation.

Table 6-4. Status Register Protection During Normal Operation

SRP1	SRP0	SRLOCK	\overline{WP}	Type of Protection	Description
0	0	x	x	Software Protected (protection is controlled by the CMPRT, BPSIZE, TB, BP[2:0], or WPS bits)	When both the SRP0 and SRP1 bits are 0, the Status registers can be written by executing a Write Status Register command (01h, 31h, 11h, 71h) and setting the WEL bit of this register. Note that the \overline{WP} pin has no meaning during this type of operation.
0	1	x	0	Hardware Protected (protection is controlled by the \overline{WP} pin)	When the SRP[1:0] bits are 0, 1 respectively, and the \overline{WP} pin is low, the registers are hardware protected and cannot be written to.
0	1	x	1	Hardware Unprotected (protection is controlled by the CMPRT, BPSIZE, TB, BP[2:0], or WPS bits)	When the SRP[1:0] bits are 0, 1 respectively, and the \overline{WP} pin is high, the registers are not hardware protected and can be written to by executing a Write Status Register command (01h, 31h, 11h, 71h) and setting the WEL bit of this register.
1	0	x	x	Reset Lockdown	When the SRP[1:0] bits are 1, 0 respectively, the Status registers are write protected and cannot be written until the device is reset (caused by a power-cycle, hardware reset, or software reset). After reset, hardware changes the state of the volatile SRP[1:0] bits to 0,0 as shown in Table 6-5 .
1	1	0	x	Reset Lockdown	When the SRP[1:0] bits are 1,1 respectively, and the SRLOCK bit is 0, the Status registers are write protected and cannot be written until the device is reset (caused by a power-cycle, hardware reset or software reset). After reset, hardware changes the state of the volatile SRP[1:0] bits to 0,1 as shown in Table 6-5 .
1	1	1	x	OTP	When the SRP[1:0] bits are 1,1 respectively, and the SRLOCK bit is 1, the Status registers are permanently write protected.

[Table 6-5](#) shows the behavior of the SRP1 and SRP0 bits after a reset condition.

Table 6-5. Status Register Protection During Reset

Non-Volatile Memory Bits			Type of Protection	Description	Volatile Register Bits	
SRP1	SRP0	SRLOCK			SRP1	SRP0
0	0	x	Software Protected	The reset operation maintains the volatile SRP1 and SRP0 at 0,0.	0	0

Table 6-5. Status Register Protection During Reset (continued)

Non-Volatile Memory Bits			Type of Protection	Description	Volatile Register Bits	
SRP1	SRP0	SRLOCK			SRP1	SRP0
0	1	x	Hardware Protected	The reset operation maintains the volatile SRP1 and SRP0 at 0,1.	0	1
1	0	x	Reset Lockdown	The reset operation changes the volatile SRP1 and SRP0 bits to 0,0.	0	0
1	1	0	Reset Lockdown	The reset operation changes the volatile SRP1 and SRP0 bits to 0,1.	0	1
1	1	1	One-Time Program (OTP)	The reset operation maintains the volatile SRP1 and SRP0 at 1,1. This makes the Status registers permanently write protected.	1	1

6.5 Status Register 3

The following table shows the bit assignments for Status register 3.

Table 6-6. Status Register 3 Format

Bit #	Acronym	Name	Type	Default	Description
7	HOLD/RESET	HOLD or RESET Function	R/W	0	<p>Adesto provides a variety of packages for the AT25XE321D as shown in Section 2. Each of these packages provides a dedicated $\overline{\text{HOLD}}$ / $\overline{\text{RESET}}$ pin that can be configured as a $\overline{\text{RESET}}$ pin, or as a $\overline{\text{HOLD}}$ pin, depending on the programming of this bit. This bit is encoded as follows:</p> <p>0: HOLD function is enabled 1: RESET function is enabled</p> <p>Note that this pin can only be configured as $\overline{\text{HOLD}}$ or $\overline{\text{RESET}}$ when the QE bit (see bit 1 of Status register 2) is cleared (logic 0). If the QE bit is set, the pin functions as a dedicated data pin and the $\overline{\text{HOLD}}$ / $\overline{\text{RESET}}$ functionality is disabled.</p>
6:5	DRV1:0	Drive Level	R/W	01 ⁽¹⁾	<p>Drive level. The DRV1 and DRV0 bits are used to determine the output driver strength during read operations. The driver strength is automatically adjusted with VCC level. The driver strength is encoded as following:</p> <p>00: Reserved 01: 100% (increase 1.66X at low VCC) 10: 66% (increase 2X at low VCC) 11: 33% (increase 3X at low VCC)</p>
4:3	R	Reserved	R	0	Reserved

Table 6-6. Status Register 3 Format (continued)

Bit #	Acronym	Name	Type	Default	Description
2	WPS	Write Protection Select	R/W	0	<p>The WPS bit selects the Write Protect scheme. This bit is encoded as follows:</p> <p>0: The AT25XE321D uses a combination of CMPRT, BPSIZE, TB, and BP[2:0] bits in Status register 1 to protect a specific area of the memory array.</p> <p>1: The AT25XE321D uses the individual block locks to protect any individual block. The default value for all individual block lock bits is 1 upon device power on or after reset.</p> <p>When this bit is set, software uses the Block Lock (36h) and Block Unlock (39h) commands to lock and unlock blocks of memory.</p> <p>For more information on this functionality, refer to Section 5.8, Memory Protection.</p>
1:0	R	Reserved	R	0	Reserved

1. Default driver strength was used for device test and characterization. In order to achieve optimal performance in user system, it is recommended to adjust driver strength setting to match user system load under application specific environmental conditions.

6.6 Status Register 4

The following table shows the bit assignments for Status register 4.

Table 6-7. Status Register 4 Format

Bit #	Acronym	Name	Type	Default	Description
7	PDM	Power Down Mode	R/W	0	<p>This bit is used in conjunction with the Deep Power Down command (B9h) to place the device into either Deep Power Down mode, or Ultra Deep Power Down mode. This bit is encoded as follows:</p> <p>0: Execution of the B9h command invokes Ultra Deep Power Down mode. This is the same as executing the UDPD command 79h. In this mode the SRAM buffer contents are not preserved.</p> <p>1: Execution of the B9h command invokes Deep Power Down mode. In this mode the SRAM buffer contents are preserved.</p> <p>In both modes, the ABh command is required to exit the corresponding Power Down mode. Simply toggling the \overline{CS} pin does not result in exiting from Power Down mode. For more information refer to Section 5.9, Power Down Considerations.</p>

Table 6-7. Status Register 4 Format (continued)

Bit #	Acronym	Name	Type	Default	Description
6	SPM	Sequential Program Mode Status	R	0	<p>The SPM bit indicates whether the device is in the Byte/Page Program mode or the Sequential Program Mode. The default state after power-up or device reset is the Byte/Page Program mode.</p> <p>This bit is encoded as follows: 0: Byte/Page Programming Mode (default) 1: Sequential Programming Mode entered</p> <p>If software sets this bit to 1, the address is only required for the first transfer of the sequential operation. Therefore, on the first transfer, command, address, and data are required. If there are subsequent operations, the address is not required. Software need only supply the command and data (on a write).</p>
5	R	Reserved	R	0	Reserved.
4	R	Reserved	R	0	Reserved.
3	XiP	XiP Mode Select	R/W	0	<p>This bit determines whether a command is required each time a read operation is executed using the E7h or EBh (Quad Read) commands. This bit is encoded as follows: 0: XiP mode (continuous read mode) is disabled 1: XiP mode (continuous read mode) is enabled</p> <p>If this bit is set and either the E7h or EBh commands are executed, the command is only required for the first access (1-4-4). In this case, the command is transferred on the SI pin, and the address and data are transferred on the SI (I/O₀), SO (I/O₁), WP (I/O₂), and HOLD (I/O₃) pins. Subsequent accesses require only address and data (0-4-4).</p> <p>Note that if either this bit or the QE bit (see bit 1 of Status register 2) is 0, the device can never be placed into 0-4-4 mode, and a command is required for each access.</p>
2:0	BWS[2:0]	Burst Wrap Settings	R	001	This 3-bit field maps to the W6:W4 bits of the Set Burst Wrap command (77h) to determine the burst wrap status and the wrap length. Refer to Section 7.14 for more information on the Set Burst Wrap command.

6.7 Status Register 5

The following table shows the bit assignments for Status register 5.

Table 6-8. Status Register 5 Format

Bit #	Acronym	Name	Type	Default	Description
7	SRLOCK	Status Register Lock	R	0	Hardware sets this bit when the user executes the Status Register Lock (6Fh) command, immediately followed by two verification bytes, 4Dh and 67h. Once this action occurs, the Status registers can be permanently locked.

Table 6-8. Status Register 5 Format (continued)

Bit #	Acronym	Name	Type	Default	Description
6:4	DC[2:0]	Dummy Clocks	R/W	000	<p>This field indicates the number of dummy clocks to be inserted between the address and data transactions for the EBh and E7h commands. Note that the dummy clocks include the 2 clocks required to clock in the M[7:0] bits.</p> <p>000: 2 clocks 001: 4 clocks 010: 6 clocks 011: 8 clocks 100: 10 clocks. 101 - 111: Reserved</p>
3	ES	Erase Suspend	R	0	<p>This bit is set by hardware whenever an erase operation is suspended.</p>
2	PS	Program Suspend	R	0	<p>This bit is set by hardware whenever a program operation is suspended.</p>
1	TERE	Terminate Enable	R/W	0	<p>The TERE bit is used to enable or disable the Terminate command. This bit is encoded as follows:</p> <p>0: Terminate command is disabled 1: Terminate command is enabled</p> <p>When the TERE bit is cleared (the default state after power-up), the Terminate command is disabled and any attempts to reset the device using the Terminate command are ignored. When the TERE bit is set, the Terminate command is enabled.</p> <p>The TERE bit retains its state as long as power is applied to the device. Once set, the TERE bit remains in that state until it is modified using the Write Status Register Byte 5 command or until the device has been power cycled.</p>
0	DWA	Doubleword Aligned	R/W	0	<p>Setting the DWA bit indicates that the devices adheres to double-word aligned addressing. This bit is only used when the E7h (XiP DWA Read) command is executed and is encoded as follows:</p> <p>0: Double-word addressing is disabled 1: Double-word addressing is enabled</p> <p>When this bit is set, the lower 2 bits of address are ignored and assumed to be 00.</p>

6.8 Status Register 6

The following table shows the bit assignments for Status register 6.

Table 6-9. Status Register 6 Format

Bit #	Acronym	Name	Type	Default	Description
7:6	LBS	Low Battery Status	R	0	<p>This 2-bit field indicates the state of the low battery test. The status is reported when the Battery Status command (EFh) is executed. This field is encoded as follows:</p> <p>00: No test in progress. Normal operation. 01: Battery test in progress. 10: Battery test complete. Result is >Vth 11: Battery test complete. Result is <Vth</p> <p>The battery threshold voltage (Vth) is selected by the user by programming bits 5:3 (LBVL) of this register. See below.</p>
5:3	LBVL	Low Battery Voltage Level	R/W	0	<p>This field sets the voltage threshold used to indicate whether the battery is OK, or nearing failure. This field is encoded as follows:</p> <p>000: 1.8V 001: 2.0V 010: 2.2V 011: 2.4V 100: 2.6V 101: 2.8V 110: 3.0V 111: 3.2V</p> <p>For example, if this field is set to 3'b110, indicating a threshold of 3.0V, and the result of the test is 2.0V, hardware would program a value of 2'b11 in the LBS field above. This indicates that the battery is below the target threshold of 3.0V and could be nearing failure.</p>
2:1	LBLD	Low Battery Load	R/W	0	<p>Load battery. This field selects the amount of load applied to the battery during the test. This field is encoded as follows:</p> <p>00: 10 μA of load 01: 100 μA of load 10: 1 mA of load 11: 10 mA of load</p> <p>Once the desired amount of loading is applied to the battery for the time determined by the state of the LBD bit below, the measured voltage is compared to the value programmed into the LBVL field in bits 5:3. The result is reported in the LBS field in bits 7:6 of this register.</p>
0	LBD	Load Battery Delay	R/W	0	<p>Load battery delay. This bit determines the amount of time the load selected by the LBLD field in bits 2:1 is applied to the battery. This bit is encoded as follows:</p> <p>0: 100 μS 1: 1 mS</p>

7. Commands and Addressing

A valid command or operation must always be started by first asserting the \overline{CS} pin. After the \overline{CS} pin has been asserted, the host controller must then clock out a valid 8-bit command on the SPI bus. Following the command, information such as address and data bytes would then be clocked out by the host controller. All command, address, and data bytes are transferred with the most-significant bit (MSB) first. An operation is ended by deasserting the \overline{CS} pin.

Commands not supported by the AT25XE321D are ignored by the device and no operation is started. The device will continue to ignore any data presented on the SI pin until the start of the next operation (\overline{CS} pin being deasserted and then reasserted). In addition, if the \overline{CS} pin is deasserted before the complete command and address information are sent to the device, then no operation is performed and the device simply returns to the idle state and waits for the next operation.

Depending on the command, up to three bytes of information may be required, representing address bits A23 - A0. Since the upper address limit of the AT25XE321D memory array is 3FFFFFFh, address bits A23 - A22 are always ignored by the device.

Table 7-10. Command Listing

Command Name	Section in Doc.	Hex Cmd	Transfer Type ⁽¹⁾		Command		Address		Dummy		Data	
			Mode	Format	Bytes	Clocks	Bytes	Clocks	Bytes	Clocks	Bytes ⁽²⁾	Clocks
Read Commands												
Read Array	7.1	03h	SPI	1-1-1	1	8	3	24	0	0	Var.	Var. x 8
Fast Read Array	7.1	0Bh	SPI	1-1-1	1	8	3	24	1	8	Var.	Var. x 8

Start Low Battery Detect	7.43	EFh	SPI	1-0-0	1	8	0	0	0	0	0	0
Read SFDP	7.44	5Ah	SPI	1-1-1	1	8	3	24	1	8	Var. ⁽¹⁹⁾	Var. x 8

1. Indicates command, address, and data, and the number of pins each type is driven on. For example, 1-1-2 indicates that the command is driven on one pin (SI), address is driven on one pin (SI), and data is driven on two pins (SI and SO).
2. Var = Variable
3. For the initial transfer of the ADh/AFh command, the command, address, and data are required. For all subsequent command, only the command and data are necessary. The address field is not required and increments automatically within the device.
4. For the 77h command, 24 bits are transferred in the address field, but these bits are don't care and are not used in the operation.
5. For the 77h command, the data byte consists of wrap bits W[7:0]. Bits 6:4 of this value are the only valid bits of the byte and are used to set the wrap mode.
6. For the D4h/84h commands, only the least significant byte of address is used. The upper 16 bits of address are don't care and are not used in the operation.
7. For the 88h command, only the upper 16 bits of address are used. The lower 8 bits are don't care and are not used in the operation.
8. For the 3Ch/3Dh command, the data byte returned provides the lock status for the 4 KB block relative to the address provided.
9. For the 9Bh and 4Bh commands, only the lower 9 bits of address (A[8:0]) are valid. Address bits 23:9 are don't care.
10. For compatibility with legacy devices, command 01h can also be used with 2 bytes of data. In such case, the second byte will be written to Status Register 2.
11. The 65h and 71h commands require only one byte of address.
12. For the 65h command, if the initial value in the address field is 01h, pointing to SR1, all of the Status registers can be read in one operation as long as the \overline{CS} pin is held low. Once the data for SR1 is fetched, hardware will increment the address automatically and fetch the contents of SR2, etc. until all six registers have been read.
13. Deep Power-Down mode can be entered by executing the B9h command with bit 7 (PDM) of Status Register 4 set.
14. Ultra Deep Power-Down mode can be entered by either executing the 79h command, or by executing the B9h command with bit 7 (PDM) of Status Register 4 cleared.
15. The 66h and 99h commands are used together and form back-to-back 1-0-0 sequences on the bus.

16. For the 90h and 94h commands, two data bytes are output. The first byte is the manufacturer ID, and the second byte is the device ID.
17. For the 9Fh command, five bytes are output. First byte is the manufacturer ID, second byte is Device ID 1, third byte is Device ID 2, fourth byte is the extended string length, and the fifth byte is the extended string value.
18. For the 25h command, the RDY/BSY status is continually output onto the SO pin as long as the $\overline{\text{CS}}$ pin remains asserted. In SPI mode 0, the number of dummy bytes/ is 0 and the number of dummy clocks is 0. In SPI mode 3, the number of dummy bytes/ is 1 and the number of dummy clocks is 8.
19. For the 5Ah command, hardware outputs the data associated with the address provided, then increments the address automatically and continues to output successive locations as long as the $\overline{\text{CS}}$ pin remains asserted. To read the entire SFDP value, software should program the initial address as 000000h to access the first address, then leave $\overline{\text{CS}}$ asserted until the entire SFDP is read out.

7.1 Read Array (03h, 0Bh)

The *Read Array* command can be used to sequentially read a continuous stream of data from the device by simply providing the clock signal once the initial starting address is specified. The device incorporates an internal address counter that automatically increments every time one byte of data is output by the device.

Two commands (0Bh and 03h) can be used to read the memory array. The use of each command depends on the maximum clock frequency that is used to read data from the device. The 0Bh command can be used at any clock frequency up to the maximum specified by f_{SCK} , and the 03h command can be used for lower frequency read operations up to the maximum specified by f_{RDLF} .

7.1.1 Command Prerequisites

None.

7.1.2 Transfer Format

The 03h/0Bh command follows the 1-1-1 transfer format described in [Section 5.2](#), where the command and address are transferred on the SI pin, and data is transferred on the SO pin. Refer to [Figure 5-6](#) for timing diagram of a 1-1-1 transfer showing the toggling of external bus signals for a read operation without dummy bytes. [Figure 5-7](#) shows a read operation with dummy bytes.

7.1.3 Transfer Sequence

To perform the *Read Array* command, the \overline{CS} pin is asserted and the information transferred as follows:

- Assert the \overline{CS} pin.
- The appropriate command (0Bh or 03h) is clocked into the device. Eight clocks are required to transfer the command. The most significant bit of the command is transferred first.
- Three address bytes are clocked in to specify the starting address location of the first byte to read within the memory array. A total of 24 clocks are required to transfer the address. The most significant bit of the address (A[23]) is transferred first.
- Following the three address bytes, an additional dummy byte must be clocked into the device if the 0Bh command is used.
- Data is output on the SO pin. Each byte transfer requires eight clock cycles. The data is always output with the most significant bit of the byte transferred first. The number of bytes transferred is determined by software. The transfer can be anywhere from a single byte to the entire memory array. The most significant bit of each data byte is transferred first.
- Deasserting the \overline{CS} pin terminates the read operation and puts the SO pin into high-impedance state. The \overline{CS} pin can be deasserted at any time and does not require a full byte of data be read.

Refer to [Table 7-10](#) for more information on the transfer sequence for this command.

When the last byte (3FFFFFFh) of the memory array has been read, the device loops back and continues reading at the beginning of the array (000000h). No delays are incurred when wrapping around from the end of the array to the beginning of the array.

7.1.4 Programming Restrictions

None

7.2 Dual Output Read Array (3Bh)

The Dual Output Read Array command is similar to the standard Read Array (03h/0Bh) command and can be used to sequentially read a continuous stream of data from the device by simply providing the clock signal once the initial starting address has been specified. Unlike the standard Read Array command, however, the Dual-Output Read Array command allows two bits of data to be clocked out of the device on every clock cycle, rather than just one.

7.2.1 Command Prerequisites

None.

7.2.2 Transfer Format

The 3Bh command follows the 1-1-2 transfer format described in [Section 5.3](#), where the command and address are transferred on the SI pin, and output data is transferred on the SI and SO pin. To facilitate this transfer, hardware switches the SI pin to an output as soon as the command has been decoded and the address transferred. Refer to [Figure 5-9](#) for a timing diagram of this command.

7.2.3 Transfer Sequence

To perform the Dual Output Read Array operation, the \overline{CS} pin is asserted and the information transferred as follows:

- The 3Bh command is clocked into the device. Eight clocks are required to transfer the command. The most significant bit of the command is transferred first.
- Three address bytes are clocked in to specify the starting address location of the first byte to read within the memory array. A total of 24 clocks are required to transfer the address. The most significant bit of the address (A[23]) is transferred first.
- Following the three address bytes, an additional dummy byte must be clocked into the device. This requires eight clock cycles to complete.
- Data is output on the SI and SO pins. As a result, each byte transfer requires four clock cycles, half that of the 03h/0Bh commands. The data is always output with the most significant bit of the byte transferred first. The number of bytes transferred is determined by software. The transfer can be anywhere from a single byte to the entire memory array. The data is driven onto the bus as follows:
 - 1st data clock: bit 7 is output on the SO pin
 - 1st data clock: bit 6 is output on the SI pin
 - 2nd data clock: bit 5 is output on the SO pin
 - 2nd data clock: bit 4 is output on the SI pin
 - 3rd data clock: bit 3 is output on the SO pin
 - 3rd data clock: bit 2 is output on the SI pin
 - 4th data clock: bit 1 is output on the SO pin
 - 4th data clock: bit 0 is output on the SI pin
 - Subsequent bytes are output with each additional 4 clocks. The sequence above continues with each byte of data being output after every four clock cycles.
- Deasserting the \overline{CS} pin terminates the read operation and puts the SO and SI pins into a high-impedance state. The \overline{CS} pin can be deasserted at any time and does not require that a full byte of data be read.

When the last byte (3FFFFFFh) of the memory array has been read, the device continues reading from the beginning of the array (000000h). No delays are incurred when wrapping around from the end of the array to the beginning of the array.

7.2.4 Programming Restrictions

None

7.3 Quad Output Read Array (6Bh)

The Quad Output Read Array command is similar to the Dual Output Read Array command, except that the Quad Output Read Array command allows four bits of data to be clocked out of the device on every clock cycle, rather than just one or two. Note that the Quad Enable bit (QE) in Status Register 2 (SR2) must be set to enable this command. The Quad Output Read Array command can be used at any clock frequency, up to the maximum specified by f_{SCK} .

7.3.1 Command Prerequisites

None.

7.3.2 Transfer Format

The 6Bh command follows the 1-1-4 transfer format described in [Section 5.4](#), where the command and address are transferred on the SI pin, and data is transferred on the \overline{HOLD} , \overline{WP} , SO, and SI pins. Refer to [Figure 5-11](#) for a timing diagram of this transaction.

7.3.3 Transfer Sequence

To perform the Quad Output Read Array operation, the \overline{CS} pin is asserted and the information transferred as follows:

- The 6Bh command is clocked into the device. Eight clocks are required to transfer the command. The most significant bit of the command is transferred first.
- Three address bytes are clocked in to specify the starting address location of the first byte to read within the memory array. A total of 24 clocks are required to transfer the address. The most significant bit of the address (A[23]) is transferred first.
- Following the three address bytes, an additional dummy byte must be clocked into the device. This requires eight clock cycles to complete.
- Following transfer of the dummy byte, hardware switches the \overline{HOLD} , \overline{WP} , and SI pins to outputs.
- Data is output on the \overline{HOLD} , \overline{WP} , SO, and SI pins. As a result, each byte transfer requires two clock cycles, one-fourth that of the 03h/0Bh commands. The data is always output with the most significant bit of the byte transferred first. The number of bytes transferred is determined by software. The transfer can be anywhere from a single byte to the entire memory array. Each data byte is shifted out of the device as follows:
 - First data clock: bit 7 is output on the \overline{HOLD} pin
 - First data clock: bit 6 is output on the \overline{WP} pin
 - First data clock: bit 5 is output on the SO pin
 - First data clock: bit 4 is output on the SI pin
 - Second data clock: bit 3 is output on the \overline{HOLD} pin
 - Second data clock: bit 2 is output on the \overline{WP} pin
 - Second data clock: bit 1 is output on the SO pin
 - Second data clock: bit 0 is output on the SI pin
- Deasserting the \overline{CS} pin terminates the read operation and puts the \overline{HOLD} , \overline{WP} , SO, SI pins into a high-impedance state. The \overline{CS} pin can be deasserted at any time and does not require that a full byte of data be read.

When the last byte (3FFFFFFh) of the memory array has been read, the device continues reading from the beginning of the array (000000h). No delays are incurred when wrapping around from the end of the array to the beginning of the array.

7.3.4 Programming Restrictions

None

7.4 XiP Mode Read (EBh), XiP Mode Read with Double-word Aligned Address (E7h)

The XiP Read command (EBh) is similar to the Quad Output Read Array command, except that four bits of address are clocked into the device on every clock cycle, rather than just one. The E7h command is similar to the EBh command but works only on double-word aligned (DWA) addresses. As such, the E7h command ignores address bits A[1:0] and internally assumes that these two bits are always 2'b00. This allows us to run the E7h command at faster clock speeds or fewer dummy clock cycles compared to the EBh command.

The EBh command can operate in either DWA mode or non-DWA mode depending on the state of the DWA bit in Status Register 5. Refer to [Section 6.7, Status Register 5](#) for more information.

7.4.1 Command Prerequisites

None.

7.4.2 Transfer Format

The initial EBh/E7h command follows the 1-4-4 transfer format described in [Section 5.6](#), where the command is transferred on the SI pin, and the address and data are transferred on the $\overline{\text{HOLD}}$, $\overline{\text{WP}}$, SO, and SI pins. Refer to [Figure 5-14](#) for a timing diagram of this command.

Subsequent EBh/E7h commands follow the 0-4-4 transfer format described in [Section 5.6](#), where the address and data are transferred on the $\overline{\text{HOLD}}$, $\overline{\text{WP}}$, SO, and SI pins. No command transfer is required. Refer to [Figure 5-15](#) for a timing diagram of this command.

7.4.3 Mode Bits

The EBh and E7h commands follow the 1-4-4 and 0-4-4 transfer formats as described above. During the initial transfer, an 8-bit mode field is transferred immediately following the last address byte and is decoded by hardware to determine if the device should be placed into XiP continuous read mode. If so, then subsequent transfers do not require the command field, resulting in a 0-4-4 transfer type. This mode increases performance by saving 8 clock cycles per transfer. For more information on this mode, refer to [Section 5.6, XiP Mode Operation](#).

7.4.4 Transfer Sequence — Initial Transfer

To perform the initial XiP Mode Read operation, the $\overline{\text{CS}}$ pin is asserted and the information transferred as follows:

- The EBh/E7h command is clocked into the device. Eight clocks are required to transfer the command. The most significant bit of the command is transferred first. This field is transferred on the SI pin.
- Three address bytes are clocked in to specify the starting address location of the first byte to read within the memory array. A total of 6 clocks are required to transfer the address. The most significant bit of the address (A[23]) is transferred first. Each address byte is shifted out of the device as follows:
 - First clock: address bit 23 is input on the $\overline{\text{HOLD}}$ pin
 - First clock: address bit 22 is input on the $\overline{\text{WP}}$ pin
 - First clock: address bit 21 is input on the SO pin
 - First clock: address bit 20 is input on the SI pin
 - Second clock: address bit 19 is input on the $\overline{\text{HOLD}}$ pin
 - Second clock: address bit 18 is input on the $\overline{\text{WP}}$ pin
 - Second clock: address bit 17 is input on the SO pin
 - Second clock: address bit 16 is input on the SI pin
 - Third and fourth clocks: A15:A8 are shifted in same as above
 - Fifth and sixth clocks: A7:A0 are shifted in same as above

- Following the three address bytes, a programmable number of dummy bytes must be clocked into the device. Refer to the [Section 7.4.6](#) below for more information. Note that the Mode bits are treated as part of the dummy bytes and must be clocked in to the device.
- Following transfer of the dummy bytes, hardware switches the $\overline{\text{HOLD}}$, $\overline{\text{WP}}$, and SI pins to outputs.
- Data is output on the $\overline{\text{HOLD}}$, $\overline{\text{WP}}$, SO, and SI pins. As a result, each byte transfer requires two clock cycles. The data is always output with the most significant bit of the byte transferred first. Each data byte is shifted out of the device as follows:
 - First clock: bit 7 is output on the $\overline{\text{HOLD}}$ pin
 - First clock: bit 6 is output on the $\overline{\text{WP}}$ pin
 - First clock: bit 5 is output on the SO pin
 - First clock: bit 4 is output on the SI pin
 - Second clock: bit 3 is output on the $\overline{\text{HOLD}}$ pin
 - Second clock: bit 2 is output on the $\overline{\text{WP}}$ pin
 - Second clock: bit 1 is output on the SO pin
 - Second clock: bit 0 is output on the SI pin
- Deasserting the $\overline{\text{CS}}$ pin terminates the read operation and puts the SI (IO₀), SO (IO₁), $\overline{\text{WP}}$ (IO₂), and $\overline{\text{HOLD}}$ (IO₃) pins into a high-impedance state. The $\overline{\text{CS}}$ pin can be deasserted at any time and does not require that a full byte of data be read.
- When the last byte (3FFFFFFh) of the memory array has been read, the device continues reading from the beginning of the array (000000h). No delays are incurred when wrapping around from the end of the array to the beginning of the array.

7.4.5 Transfer Sequence — Subsequent Transfers

To perform subsequent XiP Mode Read operations, the $\overline{\text{CS}}$ pin is asserted and the information transferred as follows:

- Three address bytes are clocked in to specify the starting address location of the first byte to read within the memory array. A total of 6 clocks are required to transfer the address. The most significant bit of the address (A[23]) is transferred first. The address is transferred on the bus in the same manner described in [Section 7.4.4](#) above.
- Following the three address bytes, a programmable number of dummy bytes must be clocked into the device. Refer to [Section 7.4.6](#) below for more information. Note that the Mode bits are treated as part of the dummy bytes and must be clocked in to the device.
- Data is output on the SI (IO₀), SO (IO₁), $\overline{\text{WP}}$ (IO₂), and $\overline{\text{HOLD}}$ (IO₃) pins. As a result, each byte transfer requires two clock cycles. The data is always output with the most significant bit of the byte transferred first. Data is shifted out onto the bus in the same manner described in [Section 7.4.4](#) above.
- Deasserting the $\overline{\text{CS}}$ pin terminates the read operation and puts the SI (IO₀), SO (IO₁), $\overline{\text{WP}}$ (IO₂), and $\overline{\text{HOLD}}$ (IO₃) pins into a high-impedance state. The $\overline{\text{CS}}$ pin can be deasserted at any time and does not require that a full byte of data be read.

When the last byte (3FFFFFFh) of the memory array has been read, the device continues reading from the beginning of the array (000000h). No delays are incurred when wrapping around from the end of the array to the beginning of the array.

7.4.6 Programmable Number of Dummy Clocks

The number of dummy clocks required differs depending on frequency and the type of command being performed and the state of bit 0 (DWA) of Status register 5. This relationship is shown in the table below. The number of Dummy clocks is set using bits 6:4 (DC[2:0]) of Status register 5. Refer to [Section 6.7, Status Register 5](#) for more information. Note that the number of dummy clocks includes the 2 SCK clock periods required to clock in the M[7:0] mode bits.

Table 7.11 Frequency and Number of Dummy Clocks Based on Command Type

Command	DWA Bit	DC[2:0]	Number of Dummy Clocks	SCK Frequency
EBh	0	000	2	30 MHz
	0	001	4	50 MHz
	0	010	6	70 MHz
	0	011	8	90 MHz
	0	100	10	104 MHz
	1	000	2	50 MHz
	1	001	4	90 MHz
	1	010	6	90 MHz
	1	011	8	90 MHz
	1	100	10	104 MHz
E7h	x	000	2	50 MHz
	x	001	4	90 MHz
	x	010	6	90 MHz
	x	011	8	90 MHz
	x	100	10	104 MHz

As shown in the above table, the EBh command can operate on both doubleword aligned (DWA = 1) and non-doubleword aligned (DWA = 0) addresses. The E7h command works only on doubleword aligned addresses, so the state of the DWA bit is ignored.

7.4.7 Programming Restrictions

None

7.5 Page Erase (81h/DBh)

The Page Erase command can be used to individually erase any page in the main memory array. The Main Memory Byte/Page Program command can be utilized at a later time.

7.5.1 Command Prerequisites

Before a Page Erase command can be issued, the Write Enable (06h) command must have been previously issued to the device to set the WEL bit of Status Register 1.

7.5.2 Transfer Format

The 81h/DBh command follows the 1-1-0 transfer format described in [Section 5.2](#), where the command and address are transferred on the SI pin. The address represents the page to be erased. Hence no data is transferred for this command.

7.5.3 Transfer Sequence

To perform the Page Erase operation, the \overline{CS} pin is asserted and the information transferred as follows:

- The 81h/DBh command is clocked into the device. Eight clocks are required to transfer the command. The most significant bit of the command is transferred first.
- Three address bytes are clocked in to specify the address location to be erased within the memory array. A total of 24 clocks are required to transfer the address. The most significant bit of the address (A[23]) is transferred first. The address is transferred as follows:
 - A[23:22] are don't care bits
 - A[21:8] contain the PA[13:0] page address bits that identifies the page to be erased
 - A[7:0] are don't care bits

When a low-to-high transition occurs on the \overline{CS} pin, the device begins the erase of the selected page (the erased state is a Logic 1).

7.5.4 Active Status Interrupt

Alternatively, the Active Status Interrupt (25h) can be used to determine when the erase operation has completed. When this command is used, it is not necessary to continuously read the \overline{RDY}/BSY bit to determine when the command has completed. Instead, hardware drives the value of the \overline{RDY}/BSY bit into the SO pin. The state of the pin is updated every clock cycle. The host can monitor the SO pin until it toggles from a logic 1 to a logic 0, indicating that the operation has completed. For more information, refer to [Section 5.14, Active Status Interrupt](#).

7.5.5 Command Status

While the device is executing a successful erase cycle, bit 0 in Status Register 1 (SR1) indicates that the device is busy. At some point before the erase cycle completes, the WEL bit in the Status Register is reset back to the logical "0" state.

7.5.6 Programming Restrictions

The Page Erase command adheres to the following programming restrictions.

- The \overline{CS} pin must be deasserted on a byte boundary (multiples of eight bits). Otherwise, the device aborts the operation and no action is taken.
- Despite the lower order address bits not being decoded by the device, the complete three address bytes must still be clocked into the device before the \overline{CS} pin is deasserted. If the address is incomplete, the operation is aborted.
- If the memory is in the protected state, the Block Erase command cannot be executed and the device returns to the idle state once the \overline{CS} pin has been deasserted.

7.6 Block Erase (20h, 52h, D8h)

A block of 4-, 32-, or 64 KBytes (KB) can be erased (all bits set to the logical “1” state) in a single operation by using one of three different forms of the Block Erase command.

- The 20h command is used for a 4 KB erase
- The 52h command is used for a 32 KB erase
- The D8h command is used for a 64 KB erase

7.6.1 Command Prerequisites

Before a Block Erase command can be issued, the Write Enable (06h) command must have been previously issued to the device to set the WEL bit of Status Register 1.

7.6.2 Transfer Format

The 20h/52h/D8h command follows the 1-1-0 transfer format described in [Section 5.2](#), where the command and address are transferred on the SI pin. The address represents the block to be erased. No data is transferred for this command.

7.6.3 Transfer Sequence

To perform the Block Erase operation, the \overline{CS} pin is asserted and the information transferred as follows:

- The appropriate command is clocked into the device. Eight clocks are required to transfer the command. The most significant bit of the command is transferred first.
- Three address bytes are clocked in to specify the address location within the 4-, 32-, or 64-KByte block to be erased. A total of 24 clocks are required to transfer the address. The most significant bit of the address (A[23]) is transferred first.

Refer to [Table 7-10](#) for more information on the transfer sequence for this command.

7.6.4 Erase Operation

When the \overline{CS} pin is deasserted, the device starts the erase of the appropriate block. The erasing of the block is internally self-timed and should take place in a time of t_{BLKE} . Since the Block Erase command erases a region of bytes, the lower order address bits do not need to be decoded by the device. Depending on the command issued, the address is treated as follows:

- For a 4 KB erase, address bits A11 - A0 are ignored by the device and their values can be either a logical “1” or “0”.
- For a 32 KB erase, address bits A14 - A0 are ignored by the device.
- For a 64 KB erase, address bits A15 - A0 are ignored by the device.

7.6.5 Command Status

While the device is executing a successful erase cycle, bit 0 in Status Register 1 (SR1) indicates that the device is busy. For faster throughput, it is recommended that Status Register 1 be polled rather than waiting the t_{BLKE} time to determine if the device has finished erasing. At some point before the erase cycle completes, the WEL bit in the Status Register is reset back to the logical “0” state.

7.6.6 Active Status Interrupt

Alternatively, the Active Status Interrupt (25h) can be used to determine when the erase operation has completed. When this command is used, it is not necessary to continuously read the \overline{RDY}/BSY bit to determine when the command has completed. Instead, hardware drives the value of the \overline{RDY}/BSY bit into the SO pin. The state of the pin is updated every clock cycle. The host can monitor the SO pin until it toggles from a logic 1 to a logic 0, indicating that the operation has completed. For more information, refer to [Section 5.14, Active Status Interrupt](#).

7.6.7 Programming Restrictions

The Block Erase commands adhere to the following programming restrictions. The following events can cause the block erase operation to be aborted. If any of these events occur, the WEL bit in Status Register 1 is reset back to the logic '0' state.

- The \overline{CS} pin must be deasserted on a byte boundary (multiples of eight bits). Otherwise, the device aborts the operation and no erase operation is performed.
- Despite the lower order address bits not being decoded by the device, the complete three address bytes must still be clocked into the device before the \overline{CS} pin is deasserted. If the address is incomplete, the operation is aborted.
- If the memory is in the protected state, the Block Erase command cannot be executed and the device returns to the idle state once the \overline{CS} pin has been deasserted.

7.7 Chip Erase (60h, C7h)

The entire memory array can be erased in a single operation by using the Chip Erase command. Two commands (60h and C7h) can be used for the Chip Erase command. There is no difference in device functionality when utilizing these two commands, so they can be used interchangeably.

7.7.1 Command Prerequisites

Before a Chip Erase command can be issued, the Write Enable (06h) command must have been previously issued to the device to set the WEL bit of Status Register 1. The Chip Erase command will not be executed if any memory region is protected by either the block protect bits or the individual block locks. For more information on the block protect bits, refer to bits 4:2 (BP[2:0]) of [Table 6.3, Status Register 1](#). For more information on enabling individual lock bits, refer to bit 2 (WPS) of [Table 6.5, Status Register 3](#).

7.7.2 Transfer Format

The 60h/C7h commands follow the 1-0-0 transfer format described in [Section 5.2](#), where the command is transferred on the SI pin. No address or data are transferred for this command. Refer to [Figure 5-2](#) for a timing diagram of this operation.

7.7.3 Transfer Sequence

To perform the Chip Erase operation, the \overline{CS} pin is asserted and the information transferred as follows:

- The 60h/C7h command is clocked into the device. Eight clocks are required to transfer the command. The most significant bit of the command is transferred first.
- When the \overline{CS} pin is deasserted, the device begins to erase the entire memory array. The erasing of the device is internally self-timed and should take place in a time of t_{CHPE} .

Refer to [Table 7-10](#) for more information on the transfer sequence for this command.

7.7.4 Device Status

While the device is executing a successful erase cycle, the \overline{RDY}/BSY bit in Status Register 1 can be read and indicates the device is busy. For faster throughput, it is recommended that Status Register 1 be polled rather than waiting the t_{CHPE} time to determine if the device has finished erasing. At some point before the erase cycle completes, the WEL bit in SR1 is reset back to the logical “0” state.

7.7.5 Active Status Interrupt

Alternatively, the Active Status Interrupt (25h) can be used to determine when the erase operation has completed. When this command is used, it is not necessary to continuously read the \overline{RDY}/BSY bit to determine when the command has completed. Instead, hardware drives the value of the \overline{RDY}/BSY bit onto the SO pin. The state of the pin is updated every clock cycle. The host can monitor the SO pin until it toggles from a logic 1 to a logic 0, indicating that the operation has completed. For more information, refer to [Section 5.14, Active Status Interrupt](#).

7.7.6 Programming Restrictions

The Chip Erase command adheres to the following programming restrictions. The following events can cause the chip erase operation to be aborted. If either one occurs, the WEL bit in Status Register 1 is reset back to the logical “0” state.

- The \overline{CS} pin must be deasserted on a byte boundary (multiple of eight bits). Otherwise, the device aborts the operation and no erase operation is performed.
- If any block in the memory is in the protected state, the Chip Erase command cannot be executed and the device returns to the idle state once the \overline{CS} pin has been deasserted.
- A Chip Erase command cannot be suspended by executing the Program/Erase Suspend (75h) command. Hardware ignores the Program/Erase Suspend command if it is issued during a Chip Erase.

7.8 Byte/Page Program (02h)

The Byte/Page Program command allows anywhere from a single byte of data to 256 bytes of data to be programmed into previously erased memory locations. An erased memory location is one that has all eight bits set to the logical “1” state (a byte value of FFh).

7.8.1 Command Prerequisites

Before a Byte/Page Program command can be issued, the Write Enable (06h) command must have been previously issued to the device to set the WEL bit of Status Register 1.

7.8.2 Transfer Format

The 02h command follows the 1-1-1 transfer format described in [Section 5.2](#), where the command, address, and data are all transferred on the SI pin. Refer to [Figure 5-8](#) for a timing diagram of this transaction.

7.8.3 Transfer Sequence

To perform the Byte/Page Program operation, the \overline{CS} pin is asserted and the information transferred as follows:

- The 02h command is clocked into the device. Eight clocks are required to transfer the command. The most significant bit of the command is transferred first.
- Three address bytes are clocked in to specify the starting address location of the first byte to read within the memory array. A total of 24 clocks are required to transfer the address. The most significant bit of the address (A[23]) is transferred first.
- Each byte transfer requires eight clock cycles. The data is always input with the most significant bit of the byte transferred first. The number of bytes transferred is determined by software. The transfer can be anywhere from a single byte to the entire buffer. If less than 256 bytes of data were sent to the device, then the remaining bytes within the page will not be programmed and remain in the erased state (FFh).
- Once the \overline{CS} pin is deasserted, hardware moves the data from the buffer to the memory. The programming of the data bytes is internally self-timed and should take place in a time of t_{PP} or t_{BP} if only programming a single byte.

Refer to [Table 7-10](#) for more information on the transfer sequence for this command.

7.8.4 Device Status

While the data is being transferred, bit 0 ($\overline{RDY/BSY}$) of Status Register 1 can be read and indicates that the device is busy. For faster throughput, it is recommended that Status Register 1 be polled rather than waiting the t_{BP} or t_{PP} time to determine if the data bytes have finished programming.

7.8.5 Active Status Interrupt

Alternatively, the Active Status Interrupt (25h) can be used to determine when the program operation has completed. When this command is used, it is not necessary to continuously read the $\overline{RDY/BSY}$ bit to determine when the command has completed. Instead, hardware drives the value of the $\overline{RDY/BSY}$ bit into the SO pin. The state of the pin is updated every clock cycle. The host can monitor the SO pin until it toggles from a logic 1 to a logic 0, indicating that the operation has completed. For more information, refer to [Section 5.14, Active Status Interrupt](#).

7.8.6 Programming Restrictions

The Byte/Page Program command adheres to the following programming restrictions. If any of the following conditions occur, the programming cycle is aborted and the WEL bit in Status Register 1 is reset back to the logic ‘0’ state.

Deassertion of the \overline{CS} Pin

The \overline{CS} pin must be deasserted on even byte boundaries (multiples of eight bits). Otherwise, the device aborts the operation and no data is programmed into the memory array.

Protected Memory

If the memory is in a protected state, then the Byte/Page Program command will not be executed, and the device returns to the idle state once the \overline{CS} pin has been deasserted.

Page Address Boundary

If the starting memory address denoted by A[23:0] does not fall on an even 256-byte page boundary (A[7:0] are not all 0), then special circumstances regarding which memory locations to be programmed will apply. In this situation, any data sent to the device that exceeds the page size wraps around back to the beginning of the same page.

For example, if the starting address denoted by A23-A0 is 0000FEh, and three bytes of data are sent to the device, then the first two bytes of data is programmed at addresses 0000FEh and 0000FFh while the last byte of data is programmed at address 000000h. The remaining bytes in the page (addresses 000001h through 0000FDh) will not be programmed and remain in the current state. In addition, if more than 256 bytes of data are sent to the device, then only the last 256 bytes sent are latched into the internal buffer.

Incomplete Address or Data

If the device receives either an incomplete address, or an incomplete data byte, the operation is aborted and hardware clears the WEL bit in Status Register 1.

7.9 Sequential Program Mode (ADh/AFh)

The Sequential Program Mode improves throughput over the Byte/Page Program command when the Byte/Page Program command is used to program single bytes only into consecutive address locations. For example, some systems may be designed to program only a single byte of information at a time and cannot utilize a buffered Page Program operation due to design restrictions. In such a case, the system would normally have to perform multiple Byte Program operations in order to program data into sequential memory locations. This approach can add considerable system overhead and SPI bus traffic.

The Sequential Programming Mode helps reduce system overhead and bus traffic by incorporating an internal address counter that keeps track of the byte location to program, thereby eliminating the need to supply an address sequence to the device for every byte being programmed.

7.9.1 Command Prerequisites

Before a Sequential Program command can be issued, the Write Enable (06h) command must have been previously issued to the device to set the WEL bit of Status Register 1.

When using the Sequential Program mode, all address locations to be programmed must be in the erased state.

7.9.2 Transfer Format

The initial ADh/AFh command follows the 1-1-1 transfer format described in [Section 5.2](#), where the command, address, and data are all transferred on the SI pin. Refer to [Figure 5-8](#) for a timing diagram of this transaction.

All subsequent ADh/AFh commands follow the 1-0-1 transfer format described in [Section 5.2](#), where the command and data are both transferred on the SI pin. Subsequent accesses do not require an address. Refer to [Figure 5-5](#) for a timing diagram of this transaction.

7.9.3 Transfer Sequence — Initial Transfer

To perform the initial Sequential Program operation, the \overline{CS} pin is asserted and the information transferred as follows:

- The AFh/ADh command is clocked into the device. Eight clocks are required to transfer the command. The most significant bit of the command is transferred first.
- Three address bytes are clocked in to specify the starting address location of the first byte to be written to within the device (typically the memory array). A total of 24 clocks are required to transfer the address. The most significant bit of the address (A[23]) is transferred first.
- Transfer the first byte of data. This requires eight clock cycles. The data is always input with the most significant bit of the byte transferred first.
- Deasserting the \overline{CS} pin starts the internally self-timed program operation, and the byte of data is programmed into the memory location specified by the A23:A0.

Refer to [Table 7-10](#) for more information on the transfer sequence for this command.

7.9.4 Transfer Sequence — Subsequent Transfers

To perform subsequent Sequential Program operations, the \overline{CS} pin is asserted and the information transferred as follows:

- The AFh/ADh command is clocked into the device. Eight clocks are required to transfer the command. The most significant bit of the command is transferred first.
- Because the initial transfer has already occurred and hardware already knows the location of the next byte to be programmed, the address field is not necessary. The command can be followed by the next data byte.
- Transfer the next byte of data. This requires eight clock cycles. The data is always input with the most significant bit of the byte transferred first.

- Deasserting the \overline{CS} pin starts the internally self-timed program operation, and the byte of data is programmed into the memory location specified by the internal address counter. There is no need to reissue the Write Enable command once the Sequential Program Mode has been entered.
- When the last desired byte has been programmed into the memory array, the Sequential Program Mode operation can be terminated by reasserting the \overline{CS} pin and sending the Write Disable command to the device to reset the WEL bit in Status Register 1.

7.9.5 Program Status

While the device is programming a byte, the \overline{RDY}/BSY bit in Status Register 1 can be read to determine if the device is busy. The programming of the data bytes is internally self-timed and should take place in a time of t_{pp} (page) or t_{BP} (single byte).

For faster throughput, it is recommended that the Status Register be polled at the end of each program cycle rather than waiting the t_{BP} or t_{pp} time to determine if the byte has finished programming before starting the next operation.

7.9.6 Commands Allowed and Not Allowed in Sequential Program Mode

When the device is busy executing a self-timed program/erase operation (\overline{RDY}/BSY bit in SR1 = 1), then it normally ignores most commands from the user. However, there are a handful of commands which are accepted by the device.

Similarly, if the device is not busy (\overline{RDY}/BSY bit in SR1 = 0), but is in Sequential Programming mode, only some commands are accepted, and others are rejected by the device.

Table 7-12 shows which commands can and cannot be executed with the device is in Sequential Program mode.

Table 7-12. Command Behavior During Sequential Programming Mode

Command Name	Command Code(s)	During Sequential Programming Mode ($\overline{RDY}/BUSY = 0$, SPM = 1)
Read Array	03h, 3Bh, 6Bh, EBh, E7h, 0Bh	Not allowed
Buffer Read	D4h	Not allowed
Page/Block Erase	81h, DBh, 20h, 52h, D8h	Not allowed
Chip Erase	60h, C7h	Not allowed
Buffer Write	84h	Not allowed
Byte/Page Program	02h, A2h, 32h	Not allowed
Buffer to M-M P-P without Erase	88h	Not allowed
Read-Modify-Write	0Ah	Not allowed
Sequential Programming	ADh, AFh	Allowed
Program/Erase Suspend	B0h, 75h	Not Allowed
Program/Erase Resume	D0h, 7Ah	Not allowed
Write Enable	06h	Allowed
Write Disable	04h	Allowed
Volatile Write Enable	50h	Not allowed
Individual Block Lock	36h	Not allowed

Table 7-12. Command Behavior During Sequential Programming Mode (continued)

Command Name	Command Code(s)	During Sequential Programming Mode (RDY/BUSY = 0, SPM = 1)
Individual Block Unlock	39h	Not allowed
Global Block Lock	7Eh	Not allowed
Global Block Unlock	98h	Not allowed
Read Block Lock Status	3Ch, 3Dh	Not allowed
Program OTP Security Register	9Bh	Not allowed
Read OTP Security Register	4Bh	Not allowed
Read Status Registers (direct)	05h, 35h, 15h	Allowed
Read Status Registers (indirect)	65h	Allowed
Write Status Registers (direct)	01h, 31h, 11h	Not allowed
Write Status Registers (indirect)	71h	Not allowed
Status Register Lock	6Fh	Not allowed
Active Interrupt	25h	Allowed
Terminate	F0h	Allowed
Enable Reset	66h	Allowed
Reset Device	99h	Allowed
Read Mfg ID and Device ID	9Fh, 90h, 94h	Allowed
Deep Power Down	B9h	Not allowed
Resume from Deep Power Down	ABh	Not allowed
Ultra Deep Power Down	79h	Not allowed
Read SFDP	5Ah	Not allowed
Set Burst with Wrap	77h	Not allowed
Start Low Battery Detect	EFh	Not allowed

7.9.7 Programming Restrictions

The Sequential Program mode adheres to the following programming restrictions.

Multiple Data Bytes per Program Cycle

If more than one byte of data is clocked in during a program cycle, then only the last byte of data sent on the SI pin is stored in the internal latches. The programming of each byte is internally self-timed and should take place in a time of t_{BP} .

Deasserting the \overline{CS} Pin

For each program cycle, a complete byte of data must be clocked into the device before the \overline{CS} pin is deasserted, and the \overline{CS} pin must be deasserted on even byte boundaries (multiples of eight bits). Otherwise, the device abort

the operation and the byte of data will not be programmed into the memory array. In addition, hardware resets the WEL bit in Status Register 1.

Protected Memory

If the address initially specified by A[23:0] points to a memory location within a block that is in the protected state, then the Sequential Program Mode command will not be executed, and the device returns to the idle state once the \overline{CS} pin has been deasserted. The WEL bit in the Status Register is also reset back to the logical “0” state.

Sequential Program mode does not automatically skip over protected blocks. Therefore, once the highest unprotected memory location in a programming sequence has been programmed, the device automatically exits the Sequential Program mode and resets the WEL bit in Status Register 1.

For example, if block 1 was protected and block 0 was currently being programmed, once the last byte of block 0 was programmed, the Sequential Program mode would automatically end. To continue programming with block 2, the Sequential Program mode would have to be restarted by supplying the ADh or AFh command, the three address bytes, and the first byte of block 2 to program.

Address Wrapping

There is no address wrapping when using the Sequential Program Mode. Therefore, when the last byte (3FFFFFFh) of the memory array has been programmed, the device automatically exits the Sequential Program mode and resets the WEL bit in Status Register 1.

64 KB Block Accesses

If during a Sequential Program operation, the address increments into a 64 KB block where an erase operation has been suspended, hardware will exit Sequential Program mode.

Clearing the WEL Bit in Status Register 1

If the WEL bit in Status register 1 is cleared at any time during a sequential programming operation, hardware will exit Sequential Program mode.

7.10 Dual Output Byte/Page Program (A2h)

The Dual Output Byte/Page Program (A2h) command is similar to the standard Byte/Page Program command (02h) and can be used to program anywhere from a single byte of data up to 256 bytes of data into previously erased memory locations. Unlike the standard Byte/Page Program command, however, the Dual Output Byte/Page Program command allows two bits of data to be clocked into the device on every clock cycle rather than just one.

7.10.1 Command Prerequisites

Before the Dual Output Byte/Page Program command can be executed, the Write Enable command (06h) must have been previously issued to set the Write Enable Latch (WEL) bit in Status Register 1.

7.10.2 Transfer Format

The A2h command follows the 1-1-2 transfer format described in [Section 5.3](#), where the command and address are transferred on the SI pin, and input data is transferred on the SI and SO pins. To facilitate this transfer, hardware switches the SO pin to an input as soon as the command has been decoded and the address transferred. Refer to [Figure 5-10](#) for a timing diagram of this transaction.

7.10.3 Transfer Sequence

To perform a Dual Output Page Program operation, the $\overline{\text{CS}}$ pin is asserted and the information transferred as follows:

- The A2h command is clocked into the device. Eight clocks are required to transfer the command. The most significant bit of the command is transferred first.
- Three address bytes are clocked in to specify the starting address location of the first byte to be written. A total of 24 clocks are required to transfer the address. The most significant bit of the address (A[23]) is transferred first.
- The first byte of data is transferred on the SI and SO pins. This requires four clock cycles. The data is always input with the most significant bit on the SO pin during each clock as shown below. Like the standard Byte/Page Program command, all data clocked into the device is stored to an internal buffer.
 - First data clock: bit 7 is input on the SO pin
 - First data clock: bit 6 is input on the SI pin
 - Second data clock: bit 5 is input on the SO pin
 - Second data clock: bit 4 is input on the SI pin
 - Third data clock: bit 3 is input on the SO pin
 - Third data clock: bit 2 is input on the SI pin
 - Fourth data clock: bit 1 is input on the SO pin
 - Fourth data clock: bit 0 is input on the SI pin
 - Subsequent data bytes are transmitted in the same sequence as above

7.10.4 Program Status

While the device is programming a byte, Status Register 1 can be read to determine if the device is busy. The programming of the data bytes is internally self-timed and should take place in a time of t_{pp} (page) or t_{bp} (single byte). For faster throughput, it is recommended that the Status Register be polled at the end of each program cycle rather than waiting the t_{bp} or t_{pp} time to determine if the byte has finished programming before starting the next operation.

7.10.5 Active Status Interrupt

Alternatively, the Active Status Interrupt (25h) can be used to determine when the program operation has completed. When this command is used, it is not necessary to continuously read the $\overline{\text{RDY}}/\text{BSY}$ bit to determine when the command has completed. Instead, hardware drives the value of the $\overline{\text{RDY}}/\text{BSY}$ bit into the SO pin. The state of the pin is updated every clock cycle. The host can monitor the SO pin until it toggles from a logic 1 to a logic 0, indicating that the operation has completed. For more information, refer to [Section 5.14, Active Status Interrupt](#).

7.10.6 Programming Restrictions

The Dual Output Byte/Page Program operation adheres to the following programming restrictions.

Page Address Boundary

If the starting memory address denoted by A[23:0] does not fall on a 256-byte page boundary (A[7:0] are not all 0), then special circumstances regarding which memory locations are to be programmed will apply. In this situation, any data sent to the device that exceeds the end of the page wraps around to the beginning of the same page.

Example: If the starting address denoted by A[23:0] is 0000FEh and three bytes of data are sent to the device, then the first two bytes of data is programmed at addresses 0000FEh and 0000FFh, while the last byte of data is programmed at address 000000h. The remaining bytes in the page (addresses 000001h through 0000FDh) will not be programmed and remain in the erased state (FFh).

Data Transfers

When the \overline{CS} pin is deasserted, the device programs the data stored in the internal buffer into the appropriate memory array locations based on the starting address specified by A[23:0] and the number of data bytes sent to the device. If fewer than 256 bytes of data is sent to the device, then the remaining bytes within the page will not be programmed and will remain in the erased state (FFh). Conversely, if more than 256 bytes of data are sent to the device, then only the last 256 bytes sent are latched into the internal buffer.

Deassertion of the \overline{CS} Pin

The three address bytes and at least one complete byte of data must be clocked into the device before the \overline{CS} pin can be deasserted. In addition, the \overline{CS} pin must be deasserted on a byte boundary (multiple of eight bits). Otherwise, the device aborts the operation and no data is programmed into the memory array.

Protected Memory

If the address specified by A[23:0] points to a memory location within a block that is in the protected state, then the Byte/Page Program command will not be executed and the device returns to the idle state once the \overline{CS} pin has been deasserted. The WEL bit in the Status Register is reset back to the Logical 0 state if the program cycle is aborted.

7.11 Quad Output Page Program (32h)

The Quad Output Page Program command allows between 1 to 256 bytes of data to be programmed at previously erased memory locations.

7.11.1 Command Prerequisites

Before a Sequential Program command can be issued, the Write Enable (06h) command must have been previously issued to the device to set the WEL bit of Status Register 1. For more information on the QE bit, refer to [Table 6.3, Status Register 1](#). In addition, the Quad Enable bit (QE bit in Status Register 2) must be set. For more information on the QE bit, refer to [Table 6.4, Status Register 2](#).

7.11.2 Transfer Format

The 32h command follows the 1-1-4 transfer format described in [Section 5.4](#), where the command and address are transferred on the SI pin, and data is transferred on the $\overline{\text{HOLD}}$, $\overline{\text{WP}}$, SO, and SI pins. Refer to [Figure 5-12](#) for a timing diagram of this operation.

7.11.3 Transfer Sequence

To perform the Quad Output Page Program operation, the $\overline{\text{CS}}$ pin is asserted and the information transferred as follows:

- The 32h command is clocked into the device. Eight clocks are required to transfer the command. The most significant bit of the command is transferred first.
- Three address bytes are clocked in to specify the starting address location of the first byte to read within the memory array. A total of 24 clocks are required to transfer the address. The most significant bit of the address (A[23]) is transferred first.
- Following transfer of the last address byte, hardware switches the SO pin to an input.
- Data is input on the $\overline{\text{HOLD}}$, $\overline{\text{WP}}$, SO, and SI pins. As a result, each byte transfer requires only two clock cycles to complete. The data is always input with the most significant bit of the byte transferred first. The number of bytes transferred is determined by software. The transfer can be anywhere from a single byte to the entire memory array. Each data byte is shifted into the device as follows:
 - First data clock: bit 7 is input on the $\overline{\text{HOLD}}$ pin
 - First data clock: bit 6 is input on the $\overline{\text{WP}}$ pin
 - First data clock: bit 5 is input on the SO pin
 - First data clock: bit 4 is input on the SI pin
 - Second data clock: bit 3 is input on the $\overline{\text{HOLD}}$ pin
 - Second data clock: bit 2 is input on the $\overline{\text{WP}}$ pin
 - Second data clock: bit 1 is input on the SO pin
 - Second data clock: bit 0 is input on the SI pin
 - Additional data bytes are transferred on the four pins in the same manner as shown above.

7.11.4 Programming Restrictions

The Quad Output Byte/Page Program command adheres to the following programming restrictions

- The $\overline{\text{CS}}$ pin must be deasserted on a byte boundary (multiples of eight bits). Otherwise, the device aborts the operation and no action is taken.
- If the memory is in a protected state, then the Byte/Page Program command will not be executed, and the device returns to the idle state once the $\overline{\text{CS}}$ pin has been deasserted.
- If the starting memory address denoted by A[23:0] does not fall on an even 256-byte page boundary (A[7:0] are not all 0), then special circumstances regarding which memory locations to be programmed will apply. In this sit-

uation, any data sent to the device that exceeds the page size wraps around back to the beginning of the same page.

For example, if the starting address denoted by A23-A0 is 0000FEh, and three bytes of data are sent to the device, then the first two bytes of data is programmed at addresses 0000FEh and 0000FFh while the last byte of data is programmed at address 000000h. The remaining bytes in the page (addresses 000001h through 0000FDh) will not be programmed and remain in the current state. In addition, if more than 256 bytes of data are sent to the device, then only the last 256 bytes sent are latched into the internal buffer.

- If the device receives either an incomplete address, or an incomplete data byte, the operation is aborted and hardware clears the WEL bit in Status Register 1.

7.12 Program/Erase Suspend (75h/B0h)

The device supports two Program/Erase Suspend commands, 75h and B0h, that perform the exact same function. The 75h command can be used for legacy software, and the B0h command is used for compatibility with future implementations.

In some code plus data storage applications, it is often necessary to process certain high-level system interrupts that require relatively immediate reading of code or data from the Flash memory. In such an instance, it may not be possible for the system to wait the microseconds or milliseconds required for the Flash memory to complete a program or erase cycle. The Program/Erase Suspend command allows a program or erase operation in progress to be suspended so that other device operations can be performed. For example, by suspending an erase operation to a particular block, the system can perform functions such as a program or read to a different block.

7.12.1 Command Prerequisites

None.

7.12.2 Transfer Format

The 75h and B0h commands follow the 1-0-0 transfer format described in [Section 5.2](#), where the command is transferred on the SI pin. No address or data are transferred for this command. Refer to [Figure 5-2](#) for a timing diagram of this operation.

7.12.3 Transfer Sequence

To perform the Program Erase/Suspend operation, the \overline{CS} pin is asserted and the information transferred as follows:

- The 75h or B0h command is clocked into the device. Eight clocks are required to transfer the command. The most significant bit of the command is transferred first.
- When the \overline{CS} pin is deasserted, the device suspends the program.

Refer to [Table 7-10](#) for more information on the transfer sequence for this command.

7.12.4 Command Behavior During a Program/Erase Operation

If an attempt is made to perform an operation that is not allowed during a program or erase suspend, such as a Write Status Register operation, then the device simply ignores the command and no operation is performed. The state of the WEL bit in Status Register 1 is not affected. Note that in the table below, the RDY/BSY bit is located in Status Register 1. The PS and ES bits are located in Status Register 5.

Table 7-13. Command Behavior During Program/Erase or Program/Erase Suspend Operations

Command	Command Code(s)	During Program or Erase (RDY/BSY = 1, PS = x, ES = x)	During Program Suspend (RDY/BSY = 0, PS = 1, ES = x)	During Erase Suspend (RDY/BSY = 0, PS = 0, ES = 1)
Read Array	03h, 0Bh, 3Bh, 6Bh, EBh, E7h	Not allowed	Allowed	Allowed
Buffer Read	D4h	Not allowed	Allowed	Allowed
Page/Block Erase	81h, DBh, 20h, 52h, D8h	Not allowed	Not allowed	Not allowed
Chip Erase	60h, C7h	Not allowed	Not allowed	Not allowed
Buffer Write	84h	Not allowed	Not allowed	Allowed
Byte/Page Program	02h, A2h, 32h	Not allowed	Not allowed	Allowed (conditionally)

Table 7-13. Command Behavior During Program/Erase or Program/Erase Suspend Operations (continued)

Command	Command Code(s)	During Program or Erase (RDY/BSY = 1, PS = x, ES = x)	During Program Suspend (RDY/BSY = 0, PS = 1, ES = x)	During Erase Suspend (RDY/BSY = 0, PS = 0, ES = 1)
Buffer to M-M P-P without Erase	88h	Not allowed	Not allowed	Allowed (conditionally)
Read-Modify-Write	58h/0Ah	Not allowed	Not allowed	Not allowed
Sequential Programming	ADh, AFh	Not allowed	Not allowed	Allowed (conditionally)
Program/Erase Suspend	B0h, 75h	Allowed	Not allowed	Not allowed
Program/Erase Resume	D0h, 7Ah	Not allowed	Allowed	Allowed
Write Enable	06h	Not allowed	Allowed	Allowed
Write Disable	04h	Not allowed	Allowed	Allowed
Volatile Write Enable	50h	Not allowed	Allowed	Allowed
Individual Block Lock	36h	Not allowed	Not allowed	Not allowed
Individual Block Unlock	39h	Not allowed	Not allowed	Not allowed
Global Block Lock	7Eh	Not allowed	Not allowed	Not allowed
Global Block Unlock	98h	Not allowed	Not allowed	Not allowed

Program OTP Security Register	9Bh	Not allowed	Not allowed	Not allowed
Read OTP Security Register	4Bh	Not allowed	Allowed	Allowed
Read Status Registers (direct)	05h, 35h, 15h	Allowed	Allowed	Allowed
Read Status Registers (indirect)	65h	Allowed	Allowed	Allowed
Write Status Registers (direct)	01h, 31h, 11h	Not allowed	Not allowed	Not allowed
Write Status Registers (indirect)	71h	Not allowed	Not allowed	Not allowed
Status Register Lock	6Fh	Not allowed	Not allowed	Not allowed
Active Interrupt	25h	Allowed	Allowed	Allowed
Terminate	F0h	Allowed	Allowed	Allowed
Enable Reset	66h	Allowed	Allowed	Allowed
Reset Device	99h	Allowed	Allowed	Allowed

Table 7-13. Command Behavior During Program/Erase or Program/Erase Suspend Operations (continued)

Command	Command Code(s)	During Program or Erase (RDY/BSY = 1, PS = x, ES = x)	During Program Suspend (RDY/BSY = 0, PS = 1, ES = x)	During Erase Suspend (RDY/BSY = 0, PS = 0, ES = 1)
Read Mfg ID and Device ID	9Fh, 90h, 94h	Allowed	Allowed	Allowed
Deep Power Down	B9h	Not allowed	Not allowed	Not allowed
Resume from Deep Power Down	ABh	Allowed	Allowed	Allowed
Ultra Deep Power Down	79h	Not allowed	Not allowed	Not allowed
Read SFDP	5Ah	Not allowed	Allowed	Allowed
Set Burst with Wrap	77h	Not allowed	Allowed	Allowed
Start Low Battery Detect	EFh	Not allowed	Allowed	Allowed

7.12.5 Device Status

When the \overline{CS} pin is deasserted, the program or erase operation currently in progress suspends within a time of t_{SUSE} . Hardware sets the Suspend (SUSP) bit in Status Register 2 and the ES or PS bits in Status Register 5 to indicate that the program or erase operation has been suspended. In addition, hardware clears the $\overline{RDY/BSY}$ bit in Status Register 1 to indicate that the device is ready for another operation.

7.12.6 Programming Restrictions

The Erase/Program Suspend command adheres to the following programming restrictions.

The following commands cannot be suspended:

- Write Status Register 1 (01h)
- Write Status Register 2 (31h)
- Write Status Register 3 (11h)
- Write Status Registers (71h)
- Status Register Lock (6Fh)
- Program OTP Security Registers (9Bh)
- Chip Erase (60h/C7h)
- Byte Write (R-M-W 0Ah)
- Sequential Programming (AFh/ADh)

Hardware ignores the Program/Suspend command if it is issued while these commands are in progress.

Erase Suspend and Program Suspend Ordering

A program operation can be performed while an erase operation is suspended. However, that operation must be completed before the erase operation can be resumed. In addition, an erase operation cannot be performed while a program operation is suspended. Other device operations, such as a Read Status Register, can also be performed while a program or erase operation is suspended.

Write Enable Latch Ignored

Since the need to suspend a program or erase operation is immediate, the Write Enable command does not need to be issued prior to the Program/Erase Suspend command being issued. Therefore, the Program/Erase Suspend command operates independently of the state of the WEL bit in the Status Register.

Deasserting the \overline{CS} Pin

The complete command must be clocked into the device before the \overline{CS} pin is deasserted. In addition, the \overline{CS} pin must be deasserted on a byte boundary (multiples of eight bits). Otherwise, no suspend operation is performed.

Accessing a Suspended Area

If a read operation is attempted to a suspended area (page for programming or block for erasing), then the device outputs undefined data. Therefore, when performing a Read Array operation to an unsuspended area and the device's internal address counter increments and crosses into the suspended area, the device starts outputting undefined data until the internal address counter crosses to an unsuspended area.

7.13 Program/Erase Resume (7Ah/D0h)

The device supports two Program/Erase Resume commands, 7Ah and D0h, that perform the exact same function. The 7Ah command can be used for legacy software, and the D0h command is used for compatibility with future implementations.

The Program/Erase Resume command allows a suspended program or erase operation to be resumed and continue programming a Flash page or erasing a Flash memory block where it left off.

7.13.1 Command Prerequisites

Hardware accepts the Program/Erase Resume command only if the ES bit (set when an erase operation is suspended) or PS bit (set when a program operation is suspended) in Status Register 5 is set and the $\overline{\text{RDY/BSY}}$ bit in Status Register 1 is cleared. If the ES/PS bit is cleared or the $\overline{\text{RDY/BSY}}$ bit is set, the Program/Erase Resume command is ignored by the device. Refer to [Table 6.3, Status Register 1](#) and [Table 6.7, Status Register 5](#).

Note that the Write Enable command does not need to be issued prior to the Program/Erase Resume command being issued. Therefore, the Program/Erase Resume command operates independently of the state of the WEL bit in Status Register 1.

7.13.2 Transfer Format

The 7Ah and D0h commands follow the 1-0-0 transfer format described in [Section 5.2](#), where the command is transferred on the SI pin. No address or data are transferred for this command. Refer to [Figure 5-2](#) for a timing diagram of this operation.

7.13.3 Transfer Sequence

To perform the Program/Erase Resume operation, the $\overline{\text{CS}}$ pin is asserted and the information transferred as follows:

- The 7Ah or D0h command is clocked into the device. Eight clocks are required to transfer the command. The most significant bit of the command is transferred first. No address or data are required for this command.
- When the $\overline{\text{CS}}$ pin is deasserted, the device resumes the program.

Refer to [Table 7-10](#) for more information on the transfer sequence for this command.

7.13.4 Command Behavior

When the command is executed, hardware performs the following:

- Hardware clears either the PS or the ES bits in Status Register 5 depending on whether a program or erase operation has been suspended. If both of these bits are cleared, hardware clears the SUSP bit in Status Register 2.
- Hardware sets the $\overline{\text{RDY/BSY}}$ bit in Status Register 1 to indicate that the device is busy.
- When the $\overline{\text{CS}}$ pin is deasserted, the program or erase operation currently suspended resumes within a time of t_{RES} .

7.13.5 Programming Restrictions

The Program/Erase Resume command adheres to the following programming restrictions.

- The complete command must be clocked into the device before the $\overline{\text{CS}}$ pin is deasserted.
- The $\overline{\text{CS}}$ pin must be deasserted on a byte boundary (multiples of eight bits). Otherwise, no resume operation is performed.
- While the device is busy resuming a program or erase operation, any attempts at issuing the Program/Erase Suspend command are ignored. Therefore, if a resumed program or erase operation needs to be subsequently suspended again, the system must either wait the entire t_{RES} time before issuing the Program/Erase Suspend command, or it can check the status of the $\overline{\text{RDY/BSY}}$ bit in Status Register 1, or the ES/PS bits in Status Register 5 to determine if the previously suspended program or erase operation has resumed.

- During a simultaneous Erase Suspend/Program Suspend condition, issuing the Program/Erase Resume command results in the program operation resuming first. After the program operation has been completed, the Program/Erase Resume command must be issued again in order for the erase operation to be resumed. For more information, refer to [Section 5.10.1, Nested Operations](#).

7.14 Set Burst Wrap (77h)

The Set Burst with Wrap (77h) command is used in conjunction with the EBh and E7h commands to support a cache line fill, regardless of the starting address. This type of operation, known as ‘address wrapping’, is an MCU-friendly feature that allows the Microcontroller Unit (MCU) cache controller to fill a cache line in one operation starting from a specific address (known as the critical byte) within the cache line, proceeding to the end of the line, then wrapping around the start of the cache line to complete the fill.

For example, if the wrap size is 16 bytes and the starting address is 0x1004, then the read sequence would be as follows: 0x1004, 0x1005, 0x1006, 0x1007, 0x1008, 0x1009, 0x100A, 0x100B, 0x100C, 0x100D, 0x100E, 0x100F, 0x1000, 0x1001, 0x1002, 0x1003. As shown in this sequence, the fill starts at address 0x1004, proceeds to the end of the cache line (0x100F), then wraps around to 0x1000 to complete the fill.

The wrap feature can improve code execution performance in the MCU system, as the MCU will first receive the command or data it requires at that instant, and then fetch the remainder of the cache line without requiring additional commands or addresses to be sent.

The 77h command is used to both enable/disable the wrap-around feature, and determine the size of the wrap. The 77h command sets the state of bits W6, W5, and W4 as shown in [Table 7.14](#).

7.14.1 Command Prerequisites

None.

7.14.2 Transfer Format

The 77h command follows the 1-4-4 transfer format described in [Section 5.6](#), where the command is transferred on the SI pin, and the address and data are transferred on the $\overline{\text{HOLD}}$, $\overline{\text{WP}}$, SO, and SI pins. Refer to [Figure 5-16](#) for a timing diagram of this command.

7.14.3 Transfer Sequence

To perform the Set Burst with Wrap operation, the $\overline{\text{CS}}$ pin is asserted and the information transferred as follows:

- The 77h command is clocked into the device. Eight clocks are required to transfer the command. The most significant bit of the command is transferred first.
- Three address bytes are clocked in. A total of 6 clocks are required to transfer the address. The most significant bit of the address (A[23]) is transferred first. Even though the address must be clocked in, the address is treated as a don't care field internally.
- Following transfer of the last address byte, eight Wrap bits are transferred which indicate the length of the wrap operation as described in the table below.

7.14.4 Wrap Bits

After the last address byte is transferred, the device transfers eight wrap bits (W7-0), which indicate the wrap length. Note that only wrap bits W6:W4 are used during this operation. The W7 and W3:W0 bits are not used. This is shown in the following table.

Table 7.14 Encoding of Burst Wrap Bits

W6	W5	W4 = 0		W4 = 1	
		Wrap Size	Wrap Around	Wrap Length	Wrap Around
0	0	8-byte	Yes	N/A	No

Table 7.14 Encoding of Burst Wrap Bits (continued)

W6	W5	W4 = 0		W4 = 1	
		Wrap Size	Wrap Around	Wrap Length	Wrap Around
0	1	16-byte	Yes	N/A	No
1	0	32-byte	Yes	N/A	No
1	1	64-byte	Yes	N/A	No

Once the 77h command is executed and the W6:W4 bits are set, the subsequent EBh or E7h command uses these bits to determine what section size to access within a given page. As shown in the table, returning to the normal read operation requires the execution of another 77h command with the W4 bit driven high (W4 = 1).

7.14.5 Programming Restrictions

The Set Burst with Wrap command adheres to the following programming restrictions.

- The \overline{CS} pin must be deasserted on a byte boundary (multiples of eight bits). Otherwise, the device aborts the operation and no action is taken.

7.15 Buffer Read (D4h)

The SRAM data buffers can be accessed independently from the main memory array using the Buffer Read command. This command allows data to be sequentially read directly from the buffer.

7.15.1 Command Prerequisites

None.

7.15.2 Transfer Format

The D4h command follows the 1-1-1 transfer format described in [Section 5.2](#), where the command and address are transferred on the SI pin, and data is transferred on the SO pin. [Figure 5-7](#) shows a buffer read operation with one dummy byte.

7.15.3 Transfer Sequence

To perform the Buffer Read operation, the \overline{CS} pin is asserted and the information transferred as follows:

- The D4 command is clocked into the device. Eight clocks are required to transfer the command. The most significant bit of the command is transferred first.
- Three address bytes are clocked in to specify the starting address location of the first byte to read within the buffer. A total of 24 clocks are required to transfer the address. The most significant bit of the address ($A[23]$) is transferred first. Since the buffer is only 256 bytes in size, the upper 16 bits of address ($A[23:8]$) are don't care for this operation. Only the lower byte ($A[7:0]$) are valid and are used to select one of the 256 buffer entries.
- Following the three address bytes, an additional dummy byte must be clocked into the device.
- Data is output on the SO pin. Each byte transfer requires eight clock cycles. The data is always output with the most significant bit of the byte transferred first. The number of bytes transferred is determined by software. The transfer can be anywhere from a single byte to the entire 256 byte buffer.
- When the end of a buffer is reached, the device continues reading back at the beginning of the buffer.
- Deasserting the \overline{CS} pin terminates the read operation and puts the SO pin into high-impedance state. The \overline{CS} pin can be deasserted at any time and does not require a full byte of data be read.

7.15.4 Programming Restrictions

None.

7.16 Buffer Write (84h)

Utilizing the Buffer Write command allows data to be written directly into the internal buffer without starting a write to the Flash array at the same time. This write operation is typically used to write small amounts of data at a time to the buffer.

To prevent buffer data loss, no program or erase operation should be performed until the written data is being used, either through the *Buffer Read* command or *Buffer to Main Memory Program without Erase* command.

7.16.1 Command Prerequisites

The Write Enable command (06h) must have been previously issued to the device to set the Write Enable Latch (WEL) bit in Status Register 1.

7.16.2 Transfer Format

The 84h command follows the 1-1-1 transfer format described in [Section 5.2](#), where the command, address, and data are transferred on the SI pin. [Figure 5-8](#) shows a buffer write operation with a one byte transfer. Additional data bytes can be transferred as long as the \overline{CS} pin remains low. Note that \overline{CS} can only be deasserted on a byte boundary.

7.16.3 Transfer Sequence

To perform the Buffer Write operation, the \overline{CS} pin is asserted and the information transferred as follows:

- The 84 command is clocked into the device. Eight clocks are required to transfer the command. The most significant bit of the command is transferred first.
- Three address bytes are clocked in to specify the starting address location of the first byte to be written within the buffer. A total of 24 clocks are required to transfer the address. The most significant bit of the address (A[23]) is transferred first. Since the buffer is only 256 bytes in size, the upper 16 bits of address (A[23:8]) are don't care for this operation. Only the lower byte (A[7:0]) is valid and is used to select one of the 256 buffer entries.
- Data is input on the SI pin. Each byte transfer requires eight clock cycles. The data is always input with the most significant bit of the byte transferred first. The number of bytes transferred is determined by software. The transfer can be anywhere from a single byte to the entire 256 byte buffer.
- After the last address byte has been clocked into the device, data can then be clocked in on subsequent clock cycles. If the end of the buffer is reached, the device wraps around back to the beginning of the buffer. Data continues to be loaded into the buffer until a low-to-high transition is detected on the \overline{CS} pin.

7.16.4 Writing Buffer Entries

Hardware does not clear the buffer entries automatically prior to starting a Buffer Write command. This allows multiple Buffer Write commands to be performed to update different parts of the buffer before writing the buffer to the Flash memory, or to update the same buffer locations multiple times before writing to Flash memory. Buffer locations which are not updated may contain whatever data is left in the buffer from the previous write operation.

7.16.5 Writing the Buffer Entries to Flash Memory

Once the Buffer Write operation is completed, the Buffer to Main Memory Page Program without Built-In Erase (88h) command is used to write the full 256-byte page, even if less than 256 bytes were written to the buffer. For more information, refer to [Section 7.17, Buffer to Main Memory Page Program without Erase \(88h\)](#).

7.16.6 Programming Restrictions

The Buffer Write command adheres to the following programming restrictions.

- The \overline{CS} pin must be deasserted on a byte boundary (multiple of eight bits). Otherwise, the device aborts the operation and no action is taken.

7.17 Buffer to Main Memory Page Program without Erase (88h)

The Buffer to Main Memory Page Program without Built-In Erase command allows data that is stored in the internal buffer to be written into a pre-erased page in the main memory array. The data in the buffer was previously written using the Buffer Write (84h) command. The 88h command writes the full 256-byte page, even if less than 256 bytes were written to the buffer.

7.17.1 Command Prerequisites

The page in main memory to be programmed must have been previously erased using one of the erase commands in order to avoid programming errors. The programming of the page is internally self-timed and should take place in a maximum time of t_{pp} .

The Write Enable command (06h) must have been previously issued to the device to set the Write Enable Latch (WEL) bit in Status Register 1.

7.17.2 Transfer Format

The 88h command follows the 1-1-0 transfer format described in [Section 5.2](#), where the command and address are transferred on the SI pin. No data is required for this operation. [Figure 5-3](#) shows a timing diagram for this type of transfer.

7.17.3 Transfer Sequence

To perform the Buffer Write operation, the \overline{CS} pin is asserted and the information transferred as follows:

- The 88h command is clocked into the device. Eight clocks are required to transfer the command. The most significant bit of the command is transferred first.
- Three address bytes are clocked in to specify the starting address location of the first byte to be written within the buffer. A total of 24 clocks are required to transfer the address. The most significant bit of the address (A[23]) is transferred first.

Since an entire 256 byte buffer entry is being written to the memory, the lower 8 bits of address (A[7:0]) are don't care for this operation, ensuring that the transfer starts at the beginning of a page boundary. Only the upper two bytes (A[23:8]) are valid and are used to select the page in memory.

- When a low-to-high transition occurs on the \overline{CS} pin, the device programs the data stored in the buffer into the specified page in the main memory.

7.17.4 Device Status

During the transfer to memory, the \overline{RDY}/BSY bit in Status Register 1 indicates that the device is busy. Hardware clears this bit to indicate that the operation has completed and the device is ready for another operation. At some point before the program cycle completes, hardware resets the WEL bit in the Status Register back to the logic '0' state.

7.17.5 Protected Memory

Note that if the memory is in the protected state, then the Buffer to Main Memory Page Program without Built-In Erase Program command will not be executed, and the device returns to the idle state once the \overline{CS} pin has been deasserted. Hardware resets the WEL bit in the Status Register back to the logical "0" state if either the program cycle aborts due to an incomplete address being sent, or because the memory location to be programmed is protected.

7.17.6 Programming Restrictions

The Buffer Main Memory Page Program without Erase command adheres to the following programming restrictions.

Protected Memory

Note that if the memory is in the protected state, then the Buffer to Main Memory Page Program without Built-In Erase Program command will not be executed, and the device returns to the idle state once the \overline{CS} pin has been deasserted.

Incomplete Address

Even though the lower 8 bits of address are not used for this command, all 24 bits of address must be transferred to the device. If an incomplete address error occurs, the program cycle aborts and hardware resets the WEL bit in Status Register 1.

Deasserting the \overline{CS} Pin

The \overline{CS} pin must be deasserted on a byte boundary (multiple of eight bits). Otherwise, the device aborts the operation and no action is taken.

7.18 Write Enable (06h)

The Write Enable command is used to set the Write Enable Latch (WEL) bit in Status Register 1. The WEL bit must be set for any of the following commands to be executed:

- Byte/Page Program (02h)
- Dual Output Byte/Page Program (A2h)
- Quad Output Byte/Page Program (32h)
- Sequential Program Mode (AFh/ADh)
- Buffer Main Memory Page Program without Erase (88h)
- Any Erase command (81h, DBh, 20h, 52h, D8h, 60h/C7h)
- Program OTP Security Register (9Bh)
- Write Status Register (01h, 31h, 11h, 71h)

This makes the issuance of the above commands a two step process, thereby reducing the chances of a command being accidentally or erroneously executed. If the WEL bit in the Status Register is not set prior to the issuance of one of these commands, that command will not be executed.

7.18.1 Command Prerequisites

None.

7.18.2 Transfer Format

The 06h command follows the 1-0-0 transfer format described in [Section 5.2](#), where the command is transferred on the SI pin. No address or data are transferred for this command. Refer to [Figure 5-2](#) for a timing diagram of this operation.

7.18.3 Transfer Sequence

To perform the Write Enable operation, the \overline{CS} pin is asserted and the information transferred as follows:

- The 06h command is clocked into the device. Eight clocks are required to transfer the command. The most significant bit of the command is transferred first. No address or data are required for this command.
- When the \overline{CS} pin is deasserted, hardware sets the WEL bit in Status Register 1.

Refer to [Table 7-10](#) for more information on the transfer sequence for this command.

7.18.4 Programming Restrictions

The Write Enable command adheres to the following programming restrictions.

- The complete command must be clocked into the device before the \overline{CS} pin is deasserted.
- The \overline{CS} pin must be deasserted on a byte boundary (multiple of eight bits). Otherwise, the device aborts the operation and no action is taken.

7.19 Write Disable (04h)

The Write Disable command is used to clear the Write Enable Latch (WEL) bit in Status Register 1. When the WEL bit is cleared, the following commands cannot be executed:

- Byte/Page Program (02h)
- Dual Output Byte/Page Program (A2h)
- Quad Output Byte/Page Program (32h)
- Sequential Program Mode (AFh/ADh)
- Buffer Main Memory Page Program without Erase (88h)
- Any Erase command (81h, DBh, 20h, 52h, D8h, 60h/C7h)
- Program OTP Security Register (9Bh)
- Write Status Register (01h, 31h, 11h, 71h)

Other conditions can also cause the WEL bit to be cleared. For more information, refer to [Section 6-2, Status Register 1 Format](#).

7.19.1 Command Prerequisites

None.

7.19.2 Transfer Format

The 04h command follows the 1-0-0 transfer format described in [Section 5.2](#), where the command is transferred on the SI pin. No address or data are transferred for this command. Refer to [Figure 5-2](#) for a timing diagram of this operation.

7.19.3 Transfer Sequence

To perform the Write Disable operation, the \overline{CS} pin is asserted and the information transferred as follows:

- The 04h command is clocked into the device. Eight clocks are required to transfer the command. The most significant bit of the command is transferred first. No address or data are required for this command.
- When the \overline{CS} pin is deasserted, hardware clears the WEL bit in Status Register 1.

Refer to [Table 7-10](#) for more information on the transfer sequence for this command.

7.19.4 Programming Restrictions

The Write Disable command adheres to the following programming restrictions.

- The complete command must be clocked into the device before the \overline{CS} pin is deasserted.
- The \overline{CS} pin must be deasserted on a byte boundary (multiple of eight bits). Otherwise, the device aborts the operation and no action is taken.

7.20 Volatile Status Register Write Enable (50h)

To write the volatile version of the Status Register bits, the Write Enable for Volatile Status Register (50h) command must be issued prior to each Write Status Register (01h) command. The Write Enable for the Volatile Status Register command does not set the Write Enable Latch (WEL) bit in Status Register 1. It is only valid for the next following Write Status Register command, to change the volatile Status Register bit values.

7.20.1 Command Prerequisites

None.

7.20.2 Transfer Format

The 50h command follows the 1-0-0 transfer format described in [Section 5.2](#), where the command is transferred on the SI pin. No address or data are transferred for this command. Refer to [Figure 5-2](#) for a timing diagram of this operation.

7.20.3 Transfer Sequence

To perform the Write Disable operation, the \overline{CS} pin is asserted and the information transferred as follows:

- The 50h command is clocked into the device. Eight clocks are required to transfer the command. The most significant bit of the command is transferred first. No address or data are required for this command.
- When the \overline{CS} pin is deasserted, hardware performs the operation.

Refer to [Table 7-10](#) for more information on the transfer sequence for this command.

7.20.4 Programming Restrictions

The Volatile Status Register Write Enable command adheres to the following programming restrictions.

- The complete command must be clocked into the device before the \overline{CS} pin is deasserted.
- The \overline{CS} pin must be deasserted on a byte boundary (multiple of eight bits). Otherwise, the device aborts the operation and no action is taken.

7.21 Individual Block Lock (36h)

The Individual Block Lock command can be used to protect individual pages in the memory array from being programmed or erased via one of the Program or Erase commands. To enable the individual block lock function, the WPS bit in Status Register 3 must be set. If the WPS bit is cleared, write protection is then determined by the combination of the CMPRT, BPSIZE, TB, and BP[2:0] bits in the Status Register 1. The default value for each individual lock bit is 1 at power-up or reset, so the entire memory array is protected.

7.21.1 Command Prerequisites

The Write Enable (06h) command must be executed before the device can accept the Individual Block Lock command. This is required to set the WEL bit in Status Register 1.

7.21.2 Transfer Format

The 36h command follows the 1-1-0 transfer format described in [Section 5.2](#), where the command and address are transferred on the SI pin. The address represents the individual block to be locked. Hence no data is transferred for this command.

7.21.3 Transfer Sequence

To perform the Individual Block Lock operation, the \overline{CS} pin is asserted and the information transferred as follows:

- The 36h command is clocked into the device. Eight clocks are required to transfer the command. The most significant bit of the command is transferred first.
- Three address bytes are clocked in to specify the address location to be locked within the memory array. A total of 24 clocks are required to transfer the address. The most significant bit of the address (A[23]) is transferred first.
- When the \overline{CS} pin is deasserted, hardware performs the operation and clears the WEL bit in Status Register 1.

Refer to [Table 7-10](#) for more information on the transfer sequence for this command.

7.21.4 Programming Restrictions

The Individual Block Lock command adheres to the following programming restrictions.

- The complete command must be clocked into the device before the \overline{CS} pin is deasserted.
- The \overline{CS} pin must be deasserted on a byte boundary (multiple of eight bits). Otherwise, the device aborts the operation and no action is taken.

7.22 Individual Block Unlock (39h)

The Individual Block Unlock command can be used to unlock individual pages in the memory array to allow them to be programmed or erased via one of the Program or Erase commands. To enable the individual block unlock function, the WPS bit in Status Register 3 must be set. If WPS is cleared, write protection is then determined by the combination of the CMP, SEC, TB, and BP[2:0] bits in Status Register 1. The default value for each individual lock bit is 1 at power-up or reset, so the entire memory array is being protected.

7.22.1 Command Prerequisites

The Write Enable (06h) command must be executed before the device can accept the Individual Block Unlock command. This is required to set the WEL bit in Status Register 1.

7.22.2 Transfer Format

The 39h command follows the 1-1-0 transfer format described in [Section 5.2](#), where the command and address are transferred on the SI pin. The address represents the individual block to be unlocked. Hence no data is transferred for this command. Refer to [Figure 5-3, SPI Transfer — Command and Address Only](#) for a timing diagram of this transaction.

7.22.3 Transfer Sequence

To perform the Individual Block Unlock operation, the \overline{CS} pin is asserted and the information transferred as follows:

- The 39h command is clocked into the device. Eight clocks are required to transfer the command. The most significant bit of the command is transferred first.
- Three address bytes are clocked in to specify the address location to be unlocked within the memory array. A total of 24 clocks are required to transfer the address. The most significant bit of the address (A[23]) is transferred first.
- When the \overline{CS} pin is deasserted, hardware performs the operation and clears the WEL bit in Status Register 1.

Refer to [Table 7-10](#) for more information on the transfer sequence for this command.

7.22.4 Programming Restrictions

The Individual Block Unlock command adheres to the following programming restrictions.

- The complete command must be clocked into the device before the \overline{CS} pin is deasserted.
- The \overline{CS} pin must be deasserted on a byte boundary (multiple of eight bits). Otherwise, the device aborts the operation and no action is taken.
-

7.23 Read Block Lock (3Ch/3Dh)

The Read Block Lock commands allow the user to read the status of the lock bits in each block. The individual block locks are used to protect any individual block. The default value for all individual block lock bits is 1 upon device power on or after reset. The 3Ch and 3Dh command perform the exact same operation. These two commands are identical and are provided for backward compatibility purposes.

7.23.1 Command Prerequisites

The WPS bit in Status Register 3 must be set. When WPS is set, software uses the Block Lock (36h) and Block Unlock (39h) commands to lock and unlock blocks of memory. If the WPS bit is cleared, write protection is determined by the combination of CMP, SEC, TB, BP[2:0] bits in the Status Registers. The Read Block Lock command must not be used to determine the protection status of any region of the memory. Refer to [Section 5.8.1](#) for more information on the protection scheme.

7.23.2 Transfer Format

The 3Ch and 3Dh commands follow the 1-1-1 transfer format described in [Section 5.2](#), where the command and address are transferred on the SI pin, and data is transferred on the SO pin. [Figure 5-6, SPI Transfer — Command, Address, and Data — Read Operation with No Dummy Bytes](#) shows a timing diagram for this transaction.

7.23.3 Transfer Sequence

To perform the Read Block Lock operation, the \overline{CS} pin is asserted and the information transferred as follows:

- The 3Ch or 3Dh command is clocked into the device. Eight clocks are required to transfer the command. The most significant bit of the command is transferred first.
- Three address bytes are clocked in to specify the starting address location of the first byte to read within the buffer. A total of 24 clocks are required to transfer the address. The most significant bit of the address (A[23]) is transferred first.
- Data is output on the SO pin and requires eight clock cycles. The MSB of the lock value is driven onto the SO pin first, and the LSB is driven out last. If the LSB is 1, the corresponding block is locked and no erase or program operation can be executed to that block. If the LSB is 0, the block is unlocked, indicating that program/erase operations are allowed. The remaining bits 7:1 of this value are undefined.

If \overline{CS} is kept low and additional data is clocked out, the device simply repeats the same byte over and over again until \overline{CS} goes high. Out of the 8 bits in this byte, the LSB (bit 0) has the lock bit information, the rest of the are undefined. The lock bit information corresponds to the region of memory that encapsulates the 20-bit address provided by the user. So for example:

- If the user provides an address of 0x000000, the device returns the lock status of the 4KB region from 0x000000 - 0x000FFF.
- If the user provides an address of 0x001234, the device returns the lock status of the 4KB region 0x001000 - 0x001FFF.

7.23.4 Programming Restrictions

The Read Block Lock command adheres to the following programming restrictions.

- The complete command must be clocked into the device before the \overline{CS} pin is deasserted.

7.24 Global Block Lock (7Eh)

The Global Block Lock command is used to set all of the block bits to 1 with one operation.

7.24.1 Command Prerequisites

The Write Enable command (06h) must be executed to set WEL bit in Status Register 1 before the Global Block Lock command can be executed. Refer to [Section 7.18, Write Enable \(06h\)](#) for more information.

7.24.2 Transfer Format

The 7Eh command follows the 1-0-0 transfer format described in [Section 5.2](#), where the command is transferred on the SI pin. No address or data are transferred for this command. Refer to [Figure 5-2](#) for a timing diagram of this operation.

7.24.3 Transfer Sequence

To perform the Global Block Lock operation, the \overline{CS} pin is asserted and the information transferred as follows:

- The 7Eh command is clocked into the device. Eight clocks are required to transfer the command. The most significant bit of the command is transferred first. No address or data are required for this command.
- When the \overline{CS} pin is deasserted, hardware performs the operation and clears the WEL bit in Status Register 1.

Refer to [Table 7-10](#) for more information on the transfer sequence for this command.

7.24.4 Programming Restrictions

The Global Block Lock command adheres to the following programming restrictions.

- The complete command must be clocked into the device before the \overline{CS} pin is deasserted.
- The \overline{CS} pin must be deasserted on a byte boundary (multiple of eight bits). Otherwise, the device aborts the operation and no action is taken.

7.25 Global Block Unlock (98h)

The Global Block UnLock command is used to reset all of the block bits to 0 with one operation.

7.25.1 Command Prerequisites

The Write Enable command (06h) must be executed to set WEL bit in Status Register 1 before the Global Block Unlock command can be executed. Refer to [Section 7.18, Write Enable \(06h\)](#) for more information.

7.25.2 Transfer Format

The 98h command follows the 1-0-0 transfer format described in [Section 5.2](#), where the command is transferred on the SI pin. No address or data are transferred for this command. Refer to [Figure 5-2](#) for a timing diagram of this operation.

7.25.3 Transfer Sequence

To perform the Global Block Unlock operation, the \overline{CS} pin is asserted and the information transferred as follows:

- The 98h command is clocked into the device. Eight clocks are required to transfer the command. The most significant bit of the command is transferred first. Since all blocks are unlocked with this command, no address or data are required.
- When the \overline{CS} pin is deasserted, hardware performs the operation and clears the WEL bit in Status Register 1.

Refer to [Table 7-10](#) for more information on the transfer sequence for this command

7.25.4 Programming Restrictions

The Global Block Unlock command adheres to the following programming restrictions.

- The complete command must be clocked into the device before the \overline{CS} pin is deasserted.
- The \overline{CS} pin must be deasserted on a byte boundary (multiple of eight bits). Otherwise, the device aborts the operation and no action is taken.

7.26 Program Security Register (9Bh)

There are four specialized 128-byte OTP (One-Time Programmable) Security Registers that can be used for purposes such as unique device serialization and locked key storage.

7.26.1 Command Prerequisites

Before the Program OTP Security Register command can be issued, the Write Enable command (06h) must be executed to set WEL bit in Status Register 1. Refer to [Section 7.18, Write Enable \(06h\)](#) for more information.

7.26.2 OTP Security Register Layout

The OTP Security Registers are independent of the main Flash memory array. The four registers are organized as follows:

Table 7-15. OTP Security Register 0 Bit Assignments

Security Register Byte Number						
127	126	125	2	1	0
Factory Programmed by Adesto						

Table 7-16. OTP Security Register 1 Bit Assignments

Security Register Byte Number						
255	254	253	130	129	128
User Security OTP Register						

Table 7-17. OTP Security Register 2 Bit Assignments

Security Register Byte Number						
383	382	381	258	257	256
User Security OTP Register						

Table 7-18. OTP Security Register 3 Bit Assignments

Security Register Byte Number						
511	510	509	386	385	384
User Security OTP Register						

7.26.3 Transfer Format

The 9Bh command follows the 1-1-1 transfer format described in [Section 5.2](#), where the command and address are transferred on the SI pin, and data is transferred on the SO pin. Refer to [Figure 5-8](#) for timing diagram of this transfer.

7.26.4 Transfer Sequence

To perform the Program OTP Register operation, the $\overline{\text{CS}}$ pin is asserted and the information transferred as follows:

- The 9Bh command is clocked into the device. Eight clocks are required to transfer the command. The most significant bit of the command is transferred first.
- Three address bytes are clocked in to specify the starting address location of the first byte to read within the memory array. A total of 24 clocks are required to transfer the address. The most significant bit of the address (A[23]) is transferred first. For this command, address bits 23:9 are don't care. Only bits 8:0 are used to address

the appropriate Security register. Refer to [Table 7-19](#) for an encoding of the address.

- Data is input on the SI pin. Each byte transfer requires eight clock cycles. The data is always input with the most significant bit of the byte transferred first. The number of bytes transferred is determined by software. The transfer can be anywhere from a single byte to the entire OTP register array. Additional data bytes are transferred every eight clocks as long as the \overline{CS} pin is asserted. The programming of the data bytes is internally self-timed and takes place in a time of t_{OTPP} if the entire 128-byte register is programmed at once.
- When the \overline{CS} pin is deasserted, the device takes the data stored in the internal buffer and programs it into the appropriate OTP Security Register locations based on the starting address specified by A8-A0 and the number of data bytes sent to the device.

Note that the Program OTP Security Register command utilizes an internal 256-buffer for processing. Therefore, the contents of the buffer is altered from its previous state when this command is issued.

Refer to [Table 7-10](#) for more information on the transfer sequence for this command.

7.26.5 Addressing the OTP Security Registers

Each byte within the four OTP security registers can be accessed using bits 8:0 of the address. Bits 23:9 of the address are ignored. The lower 7 bits (6:0) are used to select a byte within a given 128-byte OTP register. The next two bits (8:7) are used to select one of the four OTP registers. This is shown in [Figure 7-19](#).

Table 7-19. OTP Register Access Address Map

Address									
A[23:9]	A8	A7	A6	A5	A4	A3	A2	A1	A0
Don't care	0	0	OTP Security Register 0 (Factory Programmed by Adesto) A[6:0] = 0000000 - byte 0, A[6:0] = 1111111 - byte 127						
Don't care	0	1	User defined OTP Security Register 1 A[6:0] = 0000000 - byte 128, A[6:0] = 1111111 - byte 255						
Don't care	1	0	User defined OTP Security Register 2 A[6:0] = 0000000 - byte 256, A[6:0] = 1111111 - byte 383						
Don't care	1	1	User defined OTP Security Register 3 A[6:0] = 0000000 - byte 384, A[6:0] = 1111111 - byte 511						

7.26.6 Programming Status

While the device is programming the OTP Security Register, the \overline{RDY}/BSY bit in Status Register 1 can be read to determine if the operation is still in progress. For faster throughput, it is recommended that the Status Register be polled rather than waiting the t_{OTPP} time to determine if the data bytes have finished programming. At some point before the OTP Security Register programming completes, hardware clears the WEL bit in the Status Register.

Alternatively, the Active Status Interrupt can also be used to determine when the operation has finished. When this command is executed, hardware drives the state of the \overline{RDY}/BSY bit in Status Register 1 onto the SO pin. This pin can be monitored externally for a 1 to 0 transition, indicating completion of the program operation. This provides an alternative to repetitive polling of Status register 1 using the 05h command.

7.26.7 Locking OTP Registers 1 - 3

The tables above show the bytes associated with each OTP register. OTP register 0 is locked by default as the value is programmed by Adesto at the factory and cannot be changed. For OTP registers 1 - 3, the most significant byte is as follows:

- OTP Register 1: MSB = byte 255
- OTP Register 2: MSB = byte 383
- OTP Register 3: MSB = byte 511

For OTP registers 1 - 3, bit-level programming is allowed for the first 127 bytes of the registers. However, the register is locked whenever one or more bits of the most significant byte are programmed. For example, if any bit of byte 255 in OTP register 1 is programmed, that register is locked by hardware and cannot be programmed further.

7.26.8 Verifying the Locked Status of a Security Register

As described in the previous subsection, once any bit in the MSB of Security registers 1 - 3 is written, the register is locked and no further programming is allowed. Software can determine the Locked status of each register by reading bits 5:3 (SL3:SL1) of Status Register 2. Each bit corresponds to one of the user defined OTP security registers. If the corresponding bit is cleared, the register is not locked. If the corresponding bit is set, the register is locked and cannot be programmed. Refer to [Section 6.4, Status Register 2](#) for more information.

7.26.9 Programming Restrictions

The Program OTP Register command adheres to the following program restrictions.

Early Power Down

If the device is powered-down during the OTP Security Register program cycle, then the contents of the 128-byte user programmable portion of the OTP Security Register cannot be guaranteed and may not be programmed again.

Deasserting the \overline{CS} Pin

The \overline{CS} pin must be deasserted on a byte boundary (multiples of eight bits). Otherwise, the device aborts the operation and the user-programmable portion of the OTP Security Register is not programmed.

Incomplete Address or Data

The WEL bit in the Status Register is cleared if the OTP Security Register program cycle aborts due to an incomplete address being sent or an incomplete byte of data being sent.

Register Previously Programmed

Prior to programming an OTP register, hardware checks the state of the SL3:1 field in Status Register 2. For example, if an attempt is made to program OTP register 1, and the register was previously programmed as indicated by the SL1 bit in Status Register 2 being set, the operation is aborted.

7.27 Read OTP Security Register (4Bh)

The Read OTP Security Register command accesses the four specialized OTP Security registers. Any portion of the value can be read out depending on when the \overline{CS} pin is deasserted.

7.27.1 Command Prerequisites

None.

7.27.2 Transfer Format

The 4Bh command follows the 1-1-1 transfer format described in [Section 5.2](#), where the command and address are transferred on the SI pin, and data is transferred on the SO pin. Refer to [Figure 5-6](#) for a timing diagram of this transaction. In this diagram a single byte of data is shown.

7.27.3 Transfer Sequence — Single Register

To perform the Read OTP Security register operation of a single register, the \overline{CS} pin is asserted and the information transferred as follows:

- The 4Bh command is clocked into the device. Eight clocks are required to transfer the command. The most significant bit of the command is transferred first.
- Three address bytes are clocked in to specify the starting address location of the first byte to read within the memory array. A total of 24 clocks are required to transfer the address. The most significant bit of the address (A[23]) is transferred first. The address breakdown is as follows:
 - A[23:9] are don't care
 - A[8:0] indicate the byte address
- Following the three address bytes, an additional dummy byte must be clocked into the device.
- Data is output on the SO pin. Each byte transfer requires eight clock cycles. The data is always output with the most significant bit of the byte transferred first. The number of bytes transferred depends on how long the \overline{CS} pin remains asserted. A total of 1024 clocks would be required to shift out all 128 bytes of data.

7.27.4 Transfer Sequence — All Registers

To perform the Read OTP Security register operation of all four registers, the transfer sequence is the same as above, except that the \overline{CS} pin remains asserted until all registers are read. As noted above, a total of 1024 clocks would be required to read one register. Therefore, a total of 4096 clocks would be required to read out the contents of all four registers.

Refer to [Table 7-10](#) for more information on the transfer sequence for this command.

7.27.5 Programming Restrictions

None.

7.28 Read Status Registers 1 - 3 (05h, 35h, 15h)

Three Read Status Register commands are used to perform a direct read of Status registers 1 - 3. These registers can also be indirectly accessed using the 65h command as described in the following section. In the direct method, a specific command is executed. Hardware decodes this command and retrieves data from the appropriate Status register. No address field is required. Status registers 1 - 3 are accessed by the following commands.

- Read Status Register 1: 05h
- Read Status Register 2: 35h
- Read Status Register 3: 15h

7.28.1 Command Prerequisites

None.

7.28.2 Transfer Format

The 05h/35h/15h commands follow the 1-0-1 transfer format described in [Section 5.2](#), where the command is transferred on the SI pin, and data is transferred on the SO pin. No address is required for this command. Refer to [Figure 5-4](#) for a timing diagram of this transaction.

7.28.3 Transfer Sequence

To perform the Read Status Register register operation, the \overline{CS} pin is asserted and the information transferred as follows:

- The 05h/35h/15h command is clocked into the device. Eight clocks are required to transfer the command. The most significant bit of the command is transferred first.
- Data is output on the SO pin. Each byte transfer requires eight clock cycles. The data is always output with the most significant bit of the byte transferred first. After the last bit (0) of the Status Register has been clocked out, the sequence repeats itself, starting again with bit 7 of the selected register byte. This continues as long as the \overline{CS} pin remains asserted and the clock pin is being pulsed. The data in the Status Register is constantly being updated, so each repeating sequence may output new data.
- Deasserting the \overline{CS} pin terminates the Read Status Register operation and put the SO pin into a high-impedance state. The \overline{CS} pin can be deasserted at any time and does not require that a full byte of data be read.

Refer to [Table 7-10](#) for more information on the transfer sequence for this command.

7.28.4 Programming Restrictions

None.

7.29 Read Status Registers (65h)

The Read Status Register command works in conjunction with an 8-bit address field to perform an indirect read of Status registers 1 - 6. Registers 1 - 3 can also be directly accessed as described in the previous section. In the indirect method, a Read Status register command (65h) is executed. Hardware decodes this command and retrieves data from the appropriate Status register as directed by the 8-bit address field, which follows the command in the sequence. Status registers 1 - 6 are read in the following manner.

Table 7.20 Indirect Addressing of the Status Registers

Byte 0	Byte 1	Byte 2	Byte 3	Action
Command	Address	Dummy	Output	
65h	01h	Dummy	S[7:0]	Read Status Register 1
65h	02h	Dummy	S[15:8]	Read Status Register 2
65h	03h	Dummy	S[23:16]	Read Status Register 3
65h	04h	Dummy	S[31:24]	Read Status Register 4
65h	05h	Dummy	S[39:32]	Read Status Register 5
65h	06h	Dummy	S[47:40]	Read Status Register 6

7.29.1 Command Prerequisites

None.

7.29.2 Transfer Format

The 65h command follows the 1-1-1 transfer format described in [Section 5.2](#), where the command and address are transferred on the SI pin, and data is transferred on the SO pin. [Figure 7-2](#) shows a timing diagram for this operation.

7.29.3 Transfer Sequence

To perform the Read Status Register command, the \overline{CS} pin is asserted and the information transferred as follows:

- The 65h command is clocked into the device. Eight clocks are required to transfer the command. The most significant bit of the command is transferred first.
- One address byte is clocked in to specify the address the register to be written. A total of 8 clocks are required to transfer the address. The most significant bit of the address (A[7]) is transferred first.
- Following the one address byte, one dummy byte is clocked into the device.
- Data is output on the SO pin. Each byte transfer requires eight clock cycles. The data is always output with the most significant bit of the byte transferred first. The number of bytes transferred is determined by software. The transfer can be anywhere from a single register to all six registers.
- Deasserting the \overline{CS} pin terminates the read operation and puts the SO pin into high-impedance state. The \overline{CS} pin can be deasserted at any time and does not require a full byte of data be read.

Refer to [Table 7-10](#) for more information on the transfer sequence for this command.

7.29.4 Reading a Single Status Register

To read a specific Status Register, the \overline{CS} pin must first be asserted and the corresponding command of 65h must be clocked into the device. After the command has been clocked in, the 8-bit address of the register to be read is clocked into the device as shown in the above table. Once the address is decoded, hardware begins outputting Status Register data on the SO pin during every subsequent clock cycle.

7.29.5 Continuous Read of All Status Registers

To read all six Status registers in sequence, execute a 65h command with the address field equivalent to 01h. Once the contents of Status Register 1 are read out, the hardware increments the address automatically and begins reading the contents of Status Register 2. This continues until all six status registers have been read out as long as the \overline{CS} pin remains asserted and the clock pin is being pulsed. Once the process is started, data is input and output from the device as follows:

Table 7.21 Indirect Status Register Read Sequence

Clocks	Action
0 - 7	Command 65h. Clocks 0 - 3 = 0110, and clocks 4 - 7 = 0101.
8 - 15	Address 01h. Clocks 8 - 11 = 0000, and clocks 12 - 15 = 0001.
16 - 23	Dummy byte on clocks 16 - 23.
24 - 31	Status Register 1 data. Clock 24 = bit 7, and clock 31 = bit 0.
32 - 39	Status Register 2 data. Clock 32 = bit 7, and clock 39 = bit 0.
40 - 47	Status Register 3 data. Clock 40 = bit 7, and clock 47 = bit 0.
48 - 55	Status Register 4 data. Clock 48 = bit 7, and clock 55 = bit 0.
56 - 63	Status Register 5 data. Clock 56 = bit 7, and clock 63 = bit 0.
64 - 71	Status Register 6 data. Clock 64 = bit 7, and clock 71 = bit 0.
72 - xx	Data is undefined.

7.29.6 Transfer Diagram

Figure 7-2 shows the bus signals during an indirect register read operation. This type of command requires only a single 8-bit address as shown.

Figure 7-2. Status Register Read Operation Showing 8-bit Address Field

7.29.7 Programming Restrictions

The Read Status Register command adheres to the following programming restrictions.

Reading Register Addresses 7 Through 255

As the address is an 8-bit value, the device continues to read up to 255 register bytes as long as the \overline{CS} pin remains asserted, even though only six registers are implemented at this time. Starting with a read of register 7 through register 255, the device returns undefined data. If the \overline{CS} pin remains asserted and all 255 bytes are read out, the address wraps around from FFh to 00h. This continues until the \overline{CS} pin is deasserted.

7.30 Write Status Registers 1 - 3 — Direct (01h, 31h, 11h)

The Write Status Register commands are used to perform a direct write of Status registers 1 - 3. These registers can also be indirectly accessed as described in the following section. In the direct method, a specific command is executed. Hardware decodes this command and writes the data to the appropriate Status register. No address field is required. Status registers 1 - 3 are accessed by the following commands.

- Write Status Register 1: 01h
- Write Status Register 2: 31h
- Write Status Register 3: 11h

7.30.1 Command Prerequisites

To write the volatile version of the Status Register bits, the Write Enable for Volatile Status Register (50h) command must be issued prior to each Write Status Register (01h/31h/11h) command. The Write Enable for the Volatile Status Register command does not set the Write Enable Latch (WEL) bit in Status Register 1. It is only valid for the next following Write Status Register command, to change the volatile Status Register bit values.

To write the non-volatile version of the Status Register bits, the Write Enable (06h) command must be issued prior to each Write Status Register (01h/31h/11h) command.

7.30.2 Transfer Format

The 01h/31h/11h commands follow the 1-0-1 transfer format described in [Section 5.2](#), where the command and data are transferred on the SI pin. No address is required for this command. Refer to [Figure 5-5](#) for a timing diagram of this transaction.

7.30.3 Transfer Sequence

To perform the Write Status Register register operation, the \overline{CS} pin is asserted and the information transferred as follows:

- The 01h/31h/11h command is clocked into the device. Eight clocks are required to transfer the command. The most significant bit of the command is transferred first.
- Data is input on the SI pin. Each byte transfer requires eight clock cycles. The data is always input with the most significant bit of the byte transferred first.
- When the \overline{CS} pin is deasserted, hardware clears the WEL bit in Status Register 1.

Refer to [Table 7-10](#) for more information on the transfer sequence for this command.

7.30.4 Programming Restrictions

The Write Status Register command adheres to the following programming restrictions.

- The complete command must be clocked into the device before the \overline{CS} pin is deasserted.
- The \overline{CS} pin must be deasserted on a byte boundary (multiple of eight bits). Otherwise, the device aborts the operation and no action is taken.
- For compatibility with legacy devices, command 01h can also be used with 2 bytes of data. In such case, the second byte will be written to Status Register 2.
- To ensure that only Status Register 1 is written, command 01h should be used with one data byte only.

7.31 Write Status Registers — Indirect (71h)

The Write Status Register command works in conjunction with an 8-bit address field to perform an indirect write of Status registers 1 - 6. Registers 1 - 3 can also be directly accessed as described in the previous section. In the indirect method, a Write Status register command (71h) is executed. Hardware decodes this command and writes data to the appropriate Status register using the 8-bit address field, which follows the command in the sequence. Status registers 1 - 6 are written in the following manner.

Table 7.22 Indirect Addressing of the Status Registers

Byte 0	Byte 1	Byte 2	Action
Command	Address	Write Data	
71h	01h	S[7:0]	Write Status Register 1
71h	02h	S[15:8]	Write Status Register 2
71h	03h	S[23:16]	Write Status Register 3
71h	04h	S[31:24]	Write Status Register 4
71h	05h	S[39:32]	Write Status Register 5
71h	06h	S[47:40]	Write Status Register 6

7.31.1 Command Prerequisites

The Write Enable command (06h) must be executed to set WEL bit in Status Register 1 before the Write Status Register (71h) command can be executed. Refer to [Section 7.18, Write Enable \(06h\)](#) for more information.

To write the volatile version of the Status Register bits, the Write Enable for Volatile Status Register (50h) Command must be issued prior to each Write Status Register (71h) command. The Write Enable for the Volatile Status Register command does not set the Write Enable Latch (WEL) bit in Status Register 1. It is only valid for the next following Write Status Register command, to change the volatile Status Register bit values.

To write the non-volatile version of the Status Register bits, the Write Enable (06h) command must be issued prior to each Write Status Register (01h/31h/11h) command.

7.31.2 Transfer Format

The 71h command follows the 1-1-1 transfer format described in [Section 5.2](#), where the command, address, and data are transferred on the SI pin. [Figure 7-3](#) shows a timing diagram for this operation.

7.31.3 Transfer Sequence

To perform the Write Status Register operation, the \overline{CS} pin is asserted and the information transferred as follows:

- The 71h command is clocked into the device. Eight clocks are required to transfer the command. The most significant bit of the command is transferred first.
- One address byte is clocked in to specify the address of the register to be written. A total of 8 clocks are required to transfer the address. The most significant bit of the address ($A[7]$) is transferred first.
- Data is input on the SI pin. Each byte transfer requires eight clock cycles. The data is always input with the most significant bit of the byte transferred first. If more than one byte of data is provided before the \overline{CS} pin is deasserted, no register is written.

Refer to [Table 7-10](#) for more information on the transfer sequence for this command.

7.31.4 Writing to a Status Register

To write a specific Status Register, the \overline{CS} pin must first be asserted and the corresponding command of 71h must be clocked into the device. After the command has been clocked in, the 8-bit address of the register to be written is

clocked into the device as shown in the above table. Once the address is decoded, hardware begins writing to the Status Register with the data on the SI pin. This sequence in [Table 7.23](#) shows a write to Status Register 1.

Table 7.23 Indirect Status Register Write Sequence

Clocks	Action
0 - 7	Command 71h. Clocks 0 - 3 = 0111, and clocks 4 - 7 = 0001.
8 - 15	Address 01h. Clocks 8 - 11 = 0000, and clocks 12 - 15 = 0001.
16 - 23	Status Register 1 write data. Clock 16 = bit 7, and clock 23 = bit 0.

7.31.5 Transfer Diagram

[Figure 7-3](#) shows the bus signals during an indirect register write operation. This type of command requires only a single 8-bit address as shown.

Figure 7-3. Status Register Write Operation Showing 8-bit Address Field

7.31.6 Programming Restrictions

The Write Status Registers command adheres to the following programming restrictions.

- The complete command must be clocked into the device before the \overline{CS} pin is deasserted.
- The \overline{CS} pin must be deasserted on a byte boundary (multiple of eight bits). Otherwise, the device aborts the operation and no action is taken.
- The AT25XE321D device implements Status registers 1 - 6 at addresses 0x01 through 0x06. If the user attempts to write to a register that is not defined or reserved (addresses 0x00, or 0x07 - 0xFF), then the device will not write to any Status register byte. Instead the operation is aborted and hardware clears the WEL bit in Status register 1 once the \overline{CS} pin is deasserted.

7.32 Status Register Lock (6Fh)

The Status Register Lock command is used to explicitly lock the Status registers when the SRP1 and SRP0 bits in Status Registers 2 and 1 are set. Once this occurs, they can no longer be programmed. This command is provided to eliminate the possibility of inadvertently locking the registers by accidentally setting the SRP1 and SRP0 bits in Status Registers 2 and 1. Even if these two bits are set to 2'b11, this command, along with two verification bytes, is required in order for hardware to lock the Status registers.

7.32.1 Command Prerequisites

The Write Enable command (06h) must be executed to set the WEL bit in Status Register 1 before the Status Register Lock command can be executed. Refer to [Section 7.18, Write Enable \(06h\)](#) for more information.

7.32.2 Transfer Format

The 6Fh command follows a special 1-0-1 transfer format described in [Section 5.2](#), where the command, address, and data are transferred on the SI pin. However, for this command, two verification bytes are transferred. [Figure 7-4](#) shows a timing diagram for this operation.

7.32.3 Transfer Sequence

To perform the Status Register Lock operation, the \overline{CS} pin is asserted and the information transferred as follows:

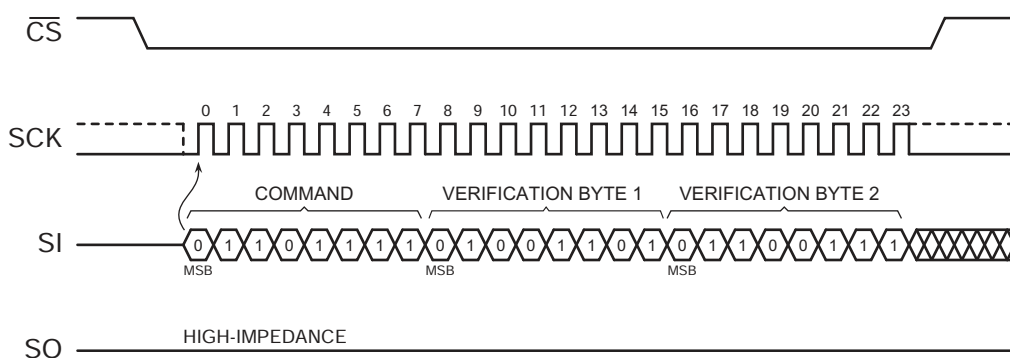

- The 6Fh command is clocked into the device. Eight clocks are required to transfer the command. The most significant bit of the command is transferred first.
- Data is input on the SI pin. The first verification byte of 4Dh is transferred, followed by a second verification byte of 67h. Each byte transfer requires eight clock cycles. The data is always input with the most significant bit of the byte transferred first. Note that these values must be transferred in the correct order. If a value other than 4Dh followed by 67h is transferred, the operation is aborted.

Refer to [Table 7-10](#) for more information on the transfer sequence for this command.

7.32.4 Transfer Diagram

[Figure 7-4](#) shows the bus signals during a Status Register Lock operation. In this transfer the command is followed by two verification bytes.

Figure 7-4. Status Register Lock Operation with Two Verification Bytes

7.32.5 Programming Restrictions

The Write Status Registers command adheres to the following programming restrictions.

- The complete command must be clocked into the device before the \overline{CS} pin is deasserted.
- The \overline{CS} pin must be deasserted on a byte boundary (multiple of eight bits). Otherwise, the device aborts the operation and no action is taken.

7.33 Deep Power Down (B9h)

The Deep Power-Down command is used in conjunction with bit 7 (PDM) in Status register 4 to place the device into Deep Power-Down mode. When the PDM bit is set and the B9h command is executed, the device enters Deep Power Down mode.

When the device is in Deep Power-Down mode, most commands, including the Read Status Register command, are ignored. The only commands that are accepted while in this mode are the Resume from Deep Power-Down command (ABh), the Enable Reset command (66h), and the Reset Device (99h) commands. Since all other commands are ignored, the mode can be used as an extra protection mechanism against program and erase operations. When the \overline{CS} pin is deasserted, the device enters the Deep Power-Down mode within the maximum time of t_{EDPD} as shown in Figure 7-5.

7.33.1 Command Prerequisites

None.

7.33.2 Transfer Format

The B9h command follows the 1-0-0 transfer format described in Section 5.2, where the command is transferred on the SI pin. No address or data are transferred for this command. Refer to Figure 5-2 for a timing diagram of this operation.

7.33.3 Transfer Sequence

To perform the Deep Power Down operation, the \overline{CS} pin is asserted and the information transferred as follows:

- The B9h command is clocked into the device. Eight clocks are required to transfer the command. The most significant bit of the command is transferred first.
- When the \overline{CS} pin is deasserted, the device begins the power down operation within the time t_{EDPD} defined in Section 8.6, AC Electrical Characteristics.

Figure 7-5 shows a diagram of this timing parameter.

Figure 7-5. Entering Deep Power Down State

Refer to Table 7-10 for more information on the transfer sequence for this command.

7.33.4 Programming Restrictions

The Deep Power Down command adheres to the following programming restrictions.

- The \overline{CS} pin must be deasserted on a byte boundary (multiple of eight bits). Otherwise, the device aborts the operation.
- The B9h command is ignored if an internally self-timed operation such as a program or erase cycle is in progress. In this case, the B9h command must be reissued after the internally self-timed operation has been completed. Software can monitor the \overline{RDY}/BSY bit in Status Register 1 to determine when the program or erase operation has completed.

7.34 Resume from Ultra-Deep Power Down / Deep Power Down with Device ID (ABh)

In order to exit the Deep Power Down (DPD) mode and resume normal device operation, the Resume from Deep Power-Down (ABh) command must be issued. This command, along with the 66h/99h Reset Enable/Reset command, are the only commands that the device recognizes while in the Deep Power-Down mode. This command allows both the exit from DPD mode, as well as a fetch of the Device ID. Which operation is executed depends on the way in which \overline{CS} is used as described below.

The ABh command can also be used to exit from Ultra-Deep Power Down (UDPD) mode. Execution of this command while in Ultra-Deep Power Down causes the device to initialize, and then enters standby mode, where it is ready to accept commands.

7.34.1 Command Options

As mentioned above, the ABh command can be used to exit both DPD and UDPD modes. In DPD mode, execution of the ABh command causes the device to exit the DPD state, and also fetch the device ID as described in [Section 7.34.4](#) below. In UDPD mode, the ABh command is used to exit the UDPD state as described in [Section 7.34.5](#) below. [Table 7-24](#) shows how to exit the DPD and UDPD modes.

Table 7-24. Options for Exiting DPD and UDPD Modes

Command	Currently in DPD Mode?	Currently in UDPD Mode?	Exit DPD Mode	Exit UDPD Mode	Fetch Device ID
ABh	No	No	No	No	Yes
	Yes	No	Yes	No	Yes
	No	Yes	No	Yes	No

7.34.2 Command Prerequisites

None.

7.34.3 Transfer Format — Resume from Deep Power Down

For this operation, the ABh command follows the 1-0-0 transfer format described in [Section 5.2](#), where the command is transferred on the SI pin. No address or data are transferred for this command. Refer to [Figure 5-2](#) for a timing diagram of this operation.

7.34.4 Transfer Format — Resume from Deep Power Down and Obtain Device ID

For this operation, the ABh command follows the 1-1-1 transfer format described in [Section 5.2](#), where the command is transferred on the SI pin and address and data on the SO pin. Refer to [Figure 5-6](#) for a timing diagram of this operation. Note that no address is transferred for this command. Rather, three dummy bytes are transferred in place of the address.

7.34.5 Transfer Sequence — Resume from Deep Power Down

To perform the Resume from Deep Power Down operation, the \overline{CS} pin is asserted and the information transferred as follows:

- The ABh command is clocked into the device. Eight clocks are required to transfer the command. The most significant bit of the command is transferred first.
- For this operation, the \overline{CS} pin must be deasserted on the 8th clock, immediately after the command is issued. This causes the device begins the resume from power down operation. When the \overline{CS} pin is deasserted after the 8th clock, the device exits the Deep Power-Down mode within the maximum time of t_{RDPD} and returns to the

standby mode. After the device has returned to the standby mode, normal command operations such as Read Array can be resumed.

Refer to [Table 7-10](#) for more information on the transfer sequence for this command.

7.34.6 Transfer Sequence — Resume from Deep Power Down and Obtain Device ID

To perform the Resume from Deep Power Down operation, the \overline{CS} pin is asserted and the information transferred as follows:

- The ABh command is clocked into the device. Eight clocks are required to transfer the command. The most significant bit of the command is transferred first.
- Three dummy bytes are then clocked in for the address. These clocks are required to provide time for the device to exit power down mode and fetch the device ID. A total of 24 clocks are required to transfer the three dummy bytes.
- For this operation, the \overline{CS} pin continues to be asserted after the 8th clock. In this operation, the \overline{CS} pin is held low for the time it takes to transfer the device ID. Therefore, 40 clocks are required to complete this operation; 8 for the command, 24 for the dummy bytes, and 8 clocks for the device ID.
- The device ID is shifted out on the SO pin, with the most significant bit of the value being transmitted first. The device ID is read out continuously until the \overline{CS} pin is deasserted.

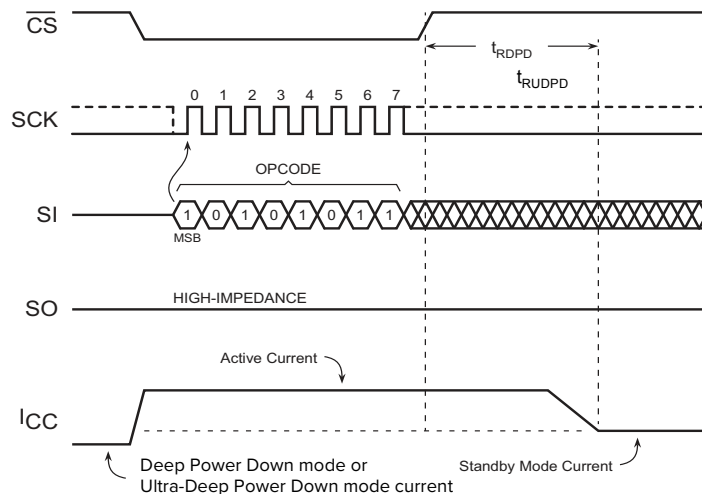

7.34.7 Transfer Sequence — Resume from Ultra-Deep Power Down

To perform the resume from Ultra-Deep Power Down operation, the \overline{CS} pin is asserted and the information transferred as follows:

- The ABh command is clocked into the device. Eight clocks are required to transfer the command. The most significant bit of the command is transferred first.
- Once \overline{CS} is deasserted, hardware initiates an internal reset of the device and the SRAM contents are lost.
- within the time t_{RUDPD} defined in Section 8.6, AC Electrical Characteristics.

[Figure 7-6](#) shows a timing diagram of this timing parameter.

Figure 7-6. Resume from Deep Power Down or Ultra-Deep Power Down

7.34.8 Programming Restrictions

The Resume from Deep Power Down command adheres to the following programming restrictions.

- The complete command must be clocked into the device before the \overline{CS} pin is deasserted.

- The \overline{CS} pin must be deasserted on a byte boundary (multiple of eight bits). Otherwise, the device aborts the operation and no action is taken.

7.35 Ultra-Deep Power Down (79h)

The Ultra-Deep Power-Down (UDPD) mode allows the device to further reduce energy consumption compared to Deep Power-Down modes by shutting down additional internal circuitry. The UDPD mode can be entered by either executing the 79h command, or by executing the B9h command with bit 7 (PDM) of Status Register 4 cleared. When the device is in the Ultra-Deep Power-Down mode, all commands except the ABh command are ignored.

Execution of the ABh command allows the device to exit from Ultra-Deep Power Down mode. Execution of this command while in Ultra-Deep Power Down causes the device to initialize, and then enters standby mode.

7.35.1 Command Prerequisites

None.

7.35.2 Transfer Format

The 79h command follows the 1-0-0 transfer format described in [Section 5.2](#), where the command is transferred on the SI pin. No address or data are transferred for this command. Refer to [Figure 5-2](#) for a timing diagram of this operation.

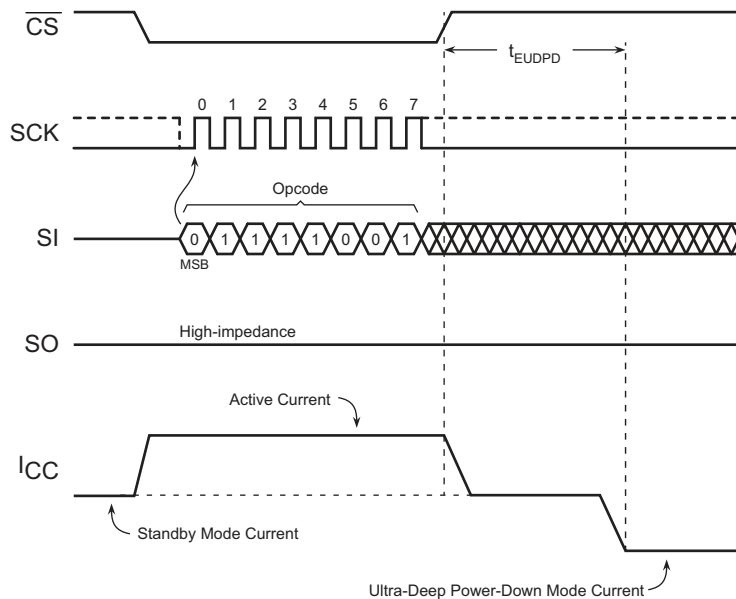

7.35.3 Transfer Sequence

To perform the Ultra-Deep Power Down operation, the \overline{CS} pin is asserted and the information transferred as follows:

- The 79h command is clocked into the device. Eight clocks are required to transfer the command. The most significant bit of the command is transferred first.
- When the \overline{CS} pin is deasserted, the device enters the Ultra-Deep Power-Down mode within the maximum time of t_{EUDPD} . Any additional data clocked into the device after this command is ignored.

[Figure 7-7](#) shows a diagram with this timing parameter.

Figure 7-7. Entering Ultra-Deep Power Down State

Refer to [Table 7-10](#) for more information on the transfer sequence for this command.

7.35.4 Programming Restrictions

The following events can cause the Ultra-Deep Power Down operation to be aborted.

- The $\overline{\text{CS}}$ pin must be deasserted on a byte boundary (multiple of eight bits). Otherwise, the device aborts the operation and return to the standby mode once the $\overline{\text{CS}}$ pin is deasserted. In addition, the device defaults to the standby mode after a power cycle.
- The 79h command is ignored if an internally self-timed operation such as a program or erase cycle is in progress. The 79h command must be reissued after the internally self-timed operation has been completed. Software can monitor the $\overline{\text{RDY/BSY}}$ bit in Status Register 1 to determine when the program or erase operation has completed.

7.36 Enable Reset (66h) and Reset Device (99h)

Executing the Reset (66h/99h) command terminates all internal operations and causes the device to initialize. After reset, the device is set to its default parameters and all previous register settings are lost.

7.36.1 Command Prerequisites

None.

7.36.2 Transfer Format

The 66h/99h commands are issued as two back-to-back 1-0-0 commands described in [Section 5.2](#). The first command (66h) enables the reset function and is transferred on the SI pin. The second command (99h) immediately follows the 66h command and initiates a reset of the device. This command is also transferred on the SI pin. No address or data are transferred for this command. Refer to [Figure 5-2](#) for a timing diagram of this operation.

7.36.3 Transfer Sequence

To perform a device reset operation, the \overline{CS} pin is asserted and the information transferred as follows:

- The 66h command is clocked into the device. Eight clocks are required to transfer the command. The most significant bit of the command is transferred first.
- Deassert the \overline{CS} pin for one clock cycle.
- Reassert the \overline{CS} pin.
- The 99h command is clocked into the device. Eight clocks are required to transfer the command. The most significant bit of the command is transferred first. Note that no other command can be issued in between the 66h command and the 99h command.
- When the \overline{CS} pin is deasserted after the 99h command, the device initiates the reset operation within a time of t_{SWRST} . During the reset sequence, no other command can be accepted by the device.

Refer to [Table 7-10](#) for more information on the transfer sequence for this command.

[Figure 7-8](#) shows an example of the back-to-back command sequence.

Figure 7-8. Enable Reset and Reset Command Sequence (SPI Mode)

7.36.4 Programming Restrictions

The Enable Reset command adheres to the following programming restrictions.

- The complete command must be clocked into the device before the \overline{CS} pin is deasserted.
- The \overline{CS} pin must be deasserted on a byte boundary (multiple of eight bits). Otherwise, the device aborts the operation and no action is taken.
- If an erase or program operation has been suspended (75h command has been executed prior to the 66h/99h command) and the device reset sequence is initiated, the data is corrupted. To prevent this from happening, check the \overline{RDY}/BSY in Status Register 1 and the SUSP bit in Status Register 2 to make sure each bit is cleared before issuing the 66h/99h Reset command sequence.

7.37 Terminate (F0h)

In some applications, it may be necessary to prematurely terminate a program or erase operation rather than wait for the program or erase operation to complete normally. The Terminate command immediately aborts any operation in progress and returns the device to an idle state.

Since the need to terminate the operation is immediate, the Write Enable command does not need to be issued prior to the Terminate command. Therefore, the Terminate command operates independently of the state of the WEL bit in Status Register 1.

Once this command is issued, the operation in progress cannot be continued. To suspend and then continue an operation, use the Program/Erase Suspend (75h) and Program/Erase Resume (7Ah) commands.

7.37.1 Command Prerequisites

The Terminate command can be executed only if the command has been enabled by setting the Reset Enabled (RSTE) bit in Status Register 5 using the Write Status Register 5 command (71h + 05h address offset). This command must be executed before the Terminate command is executed. If the Reset command has not been enabled (the RSTE bit is cleared), then any attempt at executing the Terminate command is ignored.

7.37.2 Transfer Format

The F0h command follows the 1-0-1 transfer format described in [Section 5.2](#), where the command and data are transferred on the SI pin. Immediately after the command is transferred, a confirmation data byte is transferred. This byte is required by the hardware before the Terminate command can be executed. A timing diagram of this operation is shown in [Figure 5-5](#).

7.37.3 Transfer Sequence

To perform device reset operation, the \overline{CS} pin is asserted and the information transferred as follows:

- The F0h command is clocked into the device. Eight clocks are required to transfer the command. The most significant bit of the command is transferred first.
- The D0h confirmation byte is clocked into the device. Eight clocks are required to transfer the command. The most significant bit of the command is transferred first. Note that if the confirmation byte is any value other than D0h, the entire command is ignored and the device returns to the idle state.
- When the \overline{CS} pin is deasserted after the D0h confirmation byte, the device initiates the Terminate operation within a time of t_{SWSTOP} . During the Terminate sequence, no other command can be accepted by the device.

Refer to [Table 7-10](#) for more information on the transfer sequence for this command.

7.37.4 Programming Restrictions

The F0h Terminate command adheres to the following programming restrictions.

- If a program or erase operation is in progress and cannot complete before the operation is terminated via the F0h command, the contents of the page being programmed or erased cannot be guaranteed to be valid.
- The F0h command does not reset the device configuration registers in volatile mode. If a reset of the internal state is desired, perform a 66h/99h command. This command resets the device and all programmable parameters and all volatile register contents are lost.
- The \overline{CS} pin must be deasserted on a byte boundary (multiple of eight bits). Otherwise, the device aborts the operation and returns to the standby mode once the \overline{CS} pin is deasserted. In addition, the device defaults to the standby mode after a power cycle.

7.38 Read Manufacturer/Device ID (90h)

The Read Manufacturer/Device ID (90h) command provides both the JEDEC assigned manufacturer ID, and the specific device ID.

7.38.1 Command Prerequisites

None.

7.38.2 Transfer Format

The 90h command follows the 1-1-1 transfer format described in [Section 5.2](#), where the command and address are transferred on the SI pin, and data is transferred on the SO pin. Refer to [Figure 5-6](#) for timing diagram of this operation.

7.38.3 Transfer Sequence

To perform the Read Array operation, the \overline{CS} pin is asserted and the information transferred as follows:

- The 90h command is clocked into the device. Eight clocks are required to transfer the command. The most significant bit of the command is transferred first.
- Three dummy bytes are clocked in during the address phase. A total of 24 clocks are required. These three dummy bytes are not used
- Data is output on the SO pin. Two bytes are transferred, requiring a total of 16 clock cycles. The data is driven onto the bus as follows:
 - 1st data clock: bit 7 of the manufacturer ID is output on the SO pin
 - 2nd data clock: bit 6 of the manufacturer ID is output on the SO pin
 -
 - 8th data clock: bit 0 of the manufacturer ID is output on the SO pin
 - 9th data clock: bit 7 of the device ID is output on the SO pin
 - 10th data clock: bit 6 of the device ID is output on the SO pin
 -
 - 16th data clock: bit 0 of the device ID is output on the SO pin
- Deasserting the \overline{CS} pin terminates the read operation and puts the SO pin into high-impedance state. If the \overline{CS} pin remains asserted, the device continues to shift out the manufacturer ID followed by the device ID.

Refer to [Table 7-10](#) for more information on the transfer sequence for this command.

7.38.4 Programming Restrictions

None.

7.39 Quad Read Manufacturer/Device ID (94h)

The Read Manufacturer/Device ID command operates in Quad I/O mode, where the SI, SO, \overline{WP} , and \overline{HOLD} pins are all bidirectional, to allow the manufacturer and device ID information to be transmitted at four times the speed of the Read Manufacturer/Device ID command (90h).

7.39.1 Command Prerequisites

None.

7.39.2 Transfer Format

The 94h command follows the 1-4-4 transfer format described in [Section 5.6](#), where the command is transferred on the SI pin, and the address and data are transferred on the SI, SO, \overline{WP} , and \overline{HOLD} pins. Refer to [Figure 5-14](#) for a timing diagram of this transaction.

7.39.3 Transfer Sequence

To perform the Quad Read Manufacturer/Device ID command, the \overline{CS} pin is asserted and the information transferred as follows:

- The 94h command is clocked into the device. Eight clocks are required to transfer the command. The most significant bit of the command is transferred first.
- Three dummy address bytes are clocked in during the address phase. A total of 6 clocks are required. These three dummy bytes are ignored.
- The mode byte is clocked into the device. Two clocks are required to transfer the command. The one dummy byte is ignored.
- Four dummy clocks are driven to the device prior to the output of data.
- Data is output on the SI, SO, \overline{WP} , and \overline{HOLD} pins. Each byte transfer requires two clock cycles. The data is always output with the most significant bit of the byte transferred first. The first byte transferred is the manufacturer ID. The second byte transferred is the device ID. As long as \overline{CS} is asserted, hardware continues to shift these two bytes out onto the bus. Each data byte is shifted out of the device as follows:
 - First data clock: bit 7 of the manufacturer ID is output on the \overline{HOLD} pin
 - First data clock: bit 6 of the manufacturer ID is output on the \overline{WP} pin
 - First data clock: bit 5 of the manufacturer ID is output on the SO pin
 - First data clock: bit 4 of the manufacturer ID is output on the SI pin
 - Second data clock: bit 3 of the manufacturer ID is output on the \overline{HOLD} pin
 - Second data clock: bit 2 of the manufacturer ID is output on the \overline{WP} pin
 - Second data clock: bit 1 of the manufacturer ID is output on the SO pin
 - Second data clock: bit 0 of the manufacturer ID is output on the SI pin
 - In clocks 3 and 4, the device ID is shifted out on byte 2 in the same manner as above

7.39.4 Programming Restrictions

None.

7.40 Read JEDEC ID (9Fh)

The Read JEDEC ID command allows software to identify the manufacturer and device ID information for the device while it is in the system. This command allows the ID information to be read out at a relatively low clock frequency to ensure the device can be identified. Once the identification process is complete, the application can increase the clock frequency as necessary. For more information, refer to the Serial Flash Discoverable Parameters (SFDP) JEDEC specification, edition JESD216C.

7.40.1 Command Prerequisites

None.

7.40.2 Transfer Format

The 9Fh command follows the 1-0-1 transfer format described in [Section 5.2](#), where the command is transferred on the SI pin, and data is transferred on the SO pin. Refer to [Figure 7-9](#) for timing diagram of this operation. Note that no address is required for this type of read operation.

7.40.3 Transfer Sequence

To perform the JEDEC ID operation, the \overline{CS} pin is asserted and the information transferred as follows:

- The 9Fh command is clocked into the device. Eight clocks are required to transfer the command. The most significant bit of the command is transferred first. No address is required for this transaction.
- Data is output on the SO pin. Five bytes are transferred, requiring a total of 40 clock cycles. The data is driven onto the bus as follows:
 - 1st data clock: bit 7 of the manufacturer ID is output on the SO pin
 -
 - 8th data clock: bit 0 of the manufacturer ID is output on the SO pin
 - 9th data clock: bit 7 of the device ID byte 1 is output on the SO pin
 -
 - 16th data clock: bit 0 of the device ID byte 1 is output on the SO pin
 - 17th data clock: bit 7 of the device ID byte 2 is output on the SO pin
 -
 - 24th data clock: bit 0 of the device ID byte 2 is output on the SO pin
 - 25th data clock: bit 7 of the extended device string length byte is output on the SO pin
 -
 - 32nd data clock: bit 0 of the extended device string length byte is output on the SO pin
 - 33rd data clock: bit 7 of the extended device string value byte is output on the SO pin
 -
 - 40th data clock: bit 0 of the extended device string value byte is output on the SO pin
- Deasserting the \overline{CS} pin terminates the read operation and puts the SO pin into high-impedance state. If the \overline{CS} pin remains asserted, the device continues to shift out the manufacturer ID followed by the device ID.

Refer to [Table 7-10](#) for more information on the transfer sequence for this command.

The following tables below show the exact contents of each data byte.

Table 7-25. Manufacturer and Device ID Details

Data Type	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0	Hex Value	Details
Manufacturer ID	JEDEC Assigned Code								1Fh	JEDEC Code: 0001 1111 (1Fh for Adesto)
	0	0	0	1	1	1	1	1		
Device ID (Part 1)	Family Code			Density Code					47h	Family Code: 0100 (4h) Density Code: 0111(7h)
	0	1	0	0	0	1	1	1		
Device ID (Part 2)	Sub Code			Product Version Code					0Ch	Sub Code: 0000 (0h) Product Version: 1100 (Ch)
	0	0	0	0	1	1	0	0		
Device ID (Part 3) (EDI String Length)	Number of Extended Device ID Bytes to Follow								01h	Bytes to follow: 1
	0	0	0	0	0	0	0	1		
Device ID (Part 4) (EDI String Value)	Extended device Identity Value								0xh	x: Device Variant/Option. See table below.
	0	0	0	0	x	x	x	x		

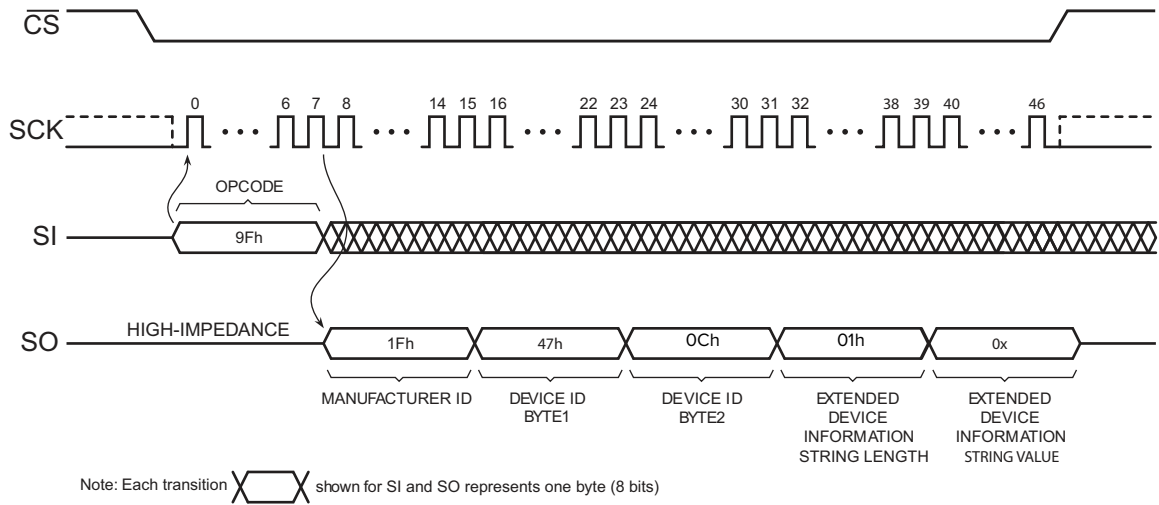

Table 7-26. Device ID Part 4 Variants — EDI String Value

EDI String Value	Variant
00h	Initial device
01h	TBD
02h	TBD
03h	TBD
04h	TBD
05h	TBD
06h	TBD
07h	TBD
08h - 0Fh	Reserved

7.40.4 Transfer Diagram

Figure 7-9 shows the bus signals during an indirect register read operation. This type of command requires only a single 8-bit address as shown.

Figure 7-9. Read JEDEC ID

7.40.5 Programming Restrictions

None.

7.41 Active Status Interrupt (25h)

To simplify the readout of the $\overline{\text{RDY}}/\text{BSY}$ bit in Status Register 1, the Active Status Interrupt command (25h) may be used. When this command is used, it is not necessary to continuously read the $\overline{\text{RDY}}/\text{BSY}$ bit to determine when the command has completed. Instead, hardware drives the value of the $\overline{\text{RDY}}/\text{BSY}$ bit into the SO pin. The state of the pin is updated in every internal clock cycle used for the self-timed operation. The host can monitor the SO pin until it toggles from a logic 1 to a logic 0, indicating that the operation has completed. At this point $\overline{\text{CS}}$ can be deasserted to complete the operation.

For example, the programming of all or part of the memory array using a command such as the Byte/Page Program (02h) can require many clock cycles to complete. In this case, once the 02h command and address have been transferred and the $\overline{\text{CS}}$ pin has been deasserted to signal the end of the bus transaction, the Active Status Interrupt command can be executed to monitor the state of the $\overline{\text{RDY}}/\text{BSY}$ bit in Status Register 1. Once the program operation has been completed internally, hardware clears the $\overline{\text{RDY}}/\text{BSY}$ bit, indicating the operation is complete. For more information, refer to [Section 5.14, Active Status Interrupt](#).

7.41.1 Command Prerequisites

None.

7.41.2 Transfer Format

The 25h command is a version of the 1-0-1 transfer format described in [Section 5.2](#), where the command is transferred on the SI pin, and data, in the form of an interrupt status, is output by the device onto the SO pin. Refer to [Figure 7-10](#) below for more information.

7.41.3 Transfer Sequence

To perform the Active Status Interrupt operation, the $\overline{\text{CS}}$ pin is asserted and the information transferred as follows:

- The 25h command is clocked into the device. Eight clocks are required to transfer the command. The most significant bit of the command is transferred first. No address is required for this transaction.
- In SPI Mode 0, no dummy clocks are required. However, for SPI Mode 3, one dummy byte is required. The value of the SI pin after the command (or dummy byte) is clocked in has no significance to the operation.
- The state of the $\overline{\text{RDY}}/\text{BSY}$ bit in Status Register 1 is output onto the SO pin, and is continuously updated by the device for as long as the $\overline{\text{CS}}$ pin remains asserted. Once the command and dummy byte are transferred, the SCK pin can be suspended. If the $\overline{\text{RDY}}/\text{BSY}$ bit changes from 1 to 0 while the $\overline{\text{CS}}$ pin is asserted, the SO line also changes from 1 to 0. Note that the $\overline{\text{RDY}}/\text{BSY}$ bit cannot change from 0 to 1 during an operation, so if the SO line is already 0, it will not change.
- Deasserting the $\overline{\text{CS}}$ pin terminates the read operation and puts the SO pin into high-impedance state. The $\overline{\text{CS}}$ pin can be deasserted at any time and does not require that a full byte of data be read.

Refer to [Table 7-10](#) for more information on the transfer sequence for this command. [Figure 7-10](#) shows the state of the SO pin during execution of an Active Status Interrupt command.

Figure 7-10. Active Status Interrupt

7.41.4 Programming Restrictions

- The \overline{CS} pin must be deasserted on a byte boundary (multiple of eight bits). Otherwise, the device aborts the operation and returns to the standby mode once the \overline{CS} pin is deasserted. In addition, the device defaults to the standby mode after a power cycle.

7.42 Single Command Read-Modify-Write — EEPROM Emulation (0Ah)

The device incorporates a completely self-contained read-modify-write operation that can be used to reprogram any number of sequential bytes in a page in the main memory array without affecting the rest of the bytes in the same page. This command allows the device to easily emulate an EEPROM by providing a method to modify a single byte or more in the main memory in a single operation, without the need for pre-erasing the memory or the need for any external RAM buffers. The main advantage of this command is that it allows a memory location to be erased and reprogrammed in one operation. For more information, refer to [Section 5.16, Read-Modify-Write](#).

7.42.1 Command Prerequisites

Before the RMW command can be issued, the Write Enable command (06h) must have been previously issued to set the WEL bit in Status Register 1.

7.42.2 Transfer Format

The transfer format for the 0Ah command is comprised of a 1-1-1 write operation as described in [Section 5.2](#). Once this command is executed, the read of the memory and subsequent modify operation are handled internally. For a timing diagram of this type of transaction, Refer to [Figure 5-8](#) for a timing diagram of this operation.

7.42.3 Transfer Sequence

To perform the RMW operation, the \overline{CS} pin is asserted and the information transferred as follows:

- The 0Ah command is clocked into the device. Eight clocks are required to transfer the command. The most significant bit of the command is transferred first.
- Three address bytes are clocked in to specify the starting address location of the first byte to read within the memory array. A total of 24 clocks are required to transfer the address. The most significant bit of the address (A[23]) is transferred first. The organization of the address field is as follows:
 - A[23:22]: These bits are don't care.
 - A[21:8]: These 14 bits specify the page in the main memory to be written.
 - A[7:0]: These address bits designate the starting byte address within the page to reprogram.
- After the address bytes have been clocked in, any number of sequential data bytes from 1 to 256 can be clocked into the device. If the end of the buffer is reached when clocking in the data, the device wraps around back to the beginning of the buffer.
- After all data bytes have been clocked into the device, a low-to-high transition on the \overline{CS} pin starts the self-contained, internal read-modify-write operation. Only the data bytes that were clocked into the device is reprogrammed in the main memory. If only one data byte was clocked into the device, then only one byte in main memory is reprogrammed and the remaining bytes in the main memory page remain in their previous state.

Refer to [Table 7-10](#) for more information on the transfer sequence for this command.

7.42.4 Programming Restrictions

The Byte Write command adheres to the following programming restrictions.

- The \overline{CS} pin must be deasserted on a byte boundary (multiples of 8 bits). Otherwise, the operation is aborted and no data is programmed. The reprogramming of the data bytes is internally self-timed. During this time, the $\overline{RDY/BSY}$ bit in Status Register 1 indicates the device is busy.

7.43 Low Battery Detect (EFh)

The low battery detect command allows software to periodically check the battery level of the system. This is most important in battery operated devices where knowing the voltage level of the battery and when it may be about to fail can be critical.

The device provides a number of programmable parameters that are used to monitor battery life in the system. The user can select at what level the battery reports a failure, how much load is applied during the test, and for how long. This flexibility allows the user to customize the battery test to their particular system requirements. For more information on how to set up the test variables and the programming sequence, refer to [Section 5.15, Low Battery Detect](#). Note that the AT25XE321D device uses Status Register 6 to monitor battery usage.

This operation supports the Active Interrupt (25h) command. This command can be used to monitor the state of the $\overline{\text{RDY}}/\text{BSY}$ bit in Status Register 1 to determine when an operation has completed. For more information, refer to [Section 7.41, Active Status Interrupt \(25h\)](#).

7.43.1 Command Prerequisites

None.

7.43.2 Transfer Format

The Low Battery Detect sequence is a two step operation. The initial EFh command follows the 1-0-0 transfer format, where the command is transferred on the SI pin. No address or data are required for this command. Refer to [Figure 5-2](#) for a timing diagram of this transfer type.

Once the operation is complete, a Status Register Read (65h) command can be used to read out the result of the battery test. Although this sequence follows the 1-1-1 format, only eight bits of address are required. For more information and a timing diagram of this type of transfer, refer to [Section 7.29.6, Transfer Diagram](#).

7.43.3 Transfer Sequence

To perform the Low Battery Detect command, the $\overline{\text{CS}}$ pin is asserted and the information transferred as follows:

- The EFh command is clocked into the device. Eight clocks are required to transfer the command. The most significant bit of the command is transferred first.
- Deassert the $\overline{\text{CS}}$ pin. Once this pin is pulled high, hardware initiates the low battery test. The parameters used for the test were previously programmed into bits 5:0 of Status Register 6.
- To execute the optional 25h command, reassert the $\overline{\text{CS}}$ pin. Drive the Active Status Interrupt (25h) command onto the SI pin.
- Deassert the $\overline{\text{CS}}$ pin. Once this pin is pulled high, hardware drives the state of the $\overline{\text{RDY}}/\text{BSY}$ bit in Status Register 1 onto the SO pin. The state of the $\overline{\text{RDY}}/\text{BSY}$ bit is updated every clock cycle. During the low battery test, the host need only to monitor a high to low transition on this pin to determine when the test has completed.
- Once a high to low transition occurs on the SO pin indicating the end of the test, the test result can be determined by driving the Read Status register (65h) command onto the SI pin. Eight clocks are required to transfer the command. The most significant bit of the command is transferred first.
- One address byte of 06h is clocked in to specify the location of Status Register 6. The most significant bit of the address ($A[7]$) is transferred first. Based on this address, hardware fetches the contents of Status Register 6 and drives the 8-bit value onto the SO pin.
- Once the contents of SR6 are driven onto the bus, the host reads bits 7:6 of this value to determine the result of the test. If this field contains a value of 2'b10, the voltage in the battery is greater than the threshold set by the LBVL field in bits 5:3. A value of 2'b11 indicates the voltage in the battery is less than the threshold set by the LBVL field.

7.43.4 Programming Restrictions

None.

7.44 Serial Flash Discoverable Parameters (5Ah)

The device contains a 256-byte Serial Flash Discoverable Parameter (SFDP) register. The SFDP register can be sequentially read in a similar fashion to the Read Array operation up to the maximum clock frequency specified by f_{SCK} .

7.44.1 Command Prerequisites

None.

7.44.2 Transfer Format

The 5Ah command follows the 1-1-1 transfer format described in Section 5.1.1, where the command, address, and dummy bytes are transferred on the SI pin, and data is transferred on the SO pin. Figure 5-6 shows a timing diagram of a read operation with dummy bytes. In this diagram one byte of data is transferred. Additional bytes can be transferred as long as the CS pin is asserted.

7.44.3 Transfer Sequence

To perform the SFDP operation, the CS pin is asserted and the information transferred as follows:

- The 5Ah command is clocked into the device. Eight clocks are required to transfer the command. The most significant bit of the command is transferred first.
- Three address bytes are clocked in to specify the starting address location of the first byte to read within the memory array. A total of 24 clocks are required to transfer the address. The most significant bit of the address (A[23]) is transferred first.
- Following the three address bytes, an additional dummy byte must be clocked into the device.
- Data is output on the SO pin. Each byte transfer requires eight clock cycles. The data is always output with the most significant bit of the byte transferred first. The number of bytes transferred is determined by software. The transfer can be anywhere from a single byte to the entire SFDP value. The most significant bit of each data byte is transferred first.
- Deasserting the CS pin terminates the read operation and puts the SO pin into high-impedance state. The CS pin can be deasserted at any time and does not require a full byte of data be read. The format of the SFDP register follows the format provided in JEDEC Standard No. 216 Rev B.

7.44.4 Programming Restrictions

When the last byte (0000FFh) of the SFDP Security Register has been read, the device continues reading back at the beginning of the register (000000h). No delays are incurred when wrapping around from the end of the register to the beginning of the register.

7.44.5 SFDP Organization

Contact Adesto for SFDP table information.

8. Electrical Specifications

8.1 Absolute Maximum Ratings

Temperature under bias	-55 °C to +125 °C
Storage Temperature	-65 °C to +150 °C
All input voltages (including NC pins) with respect to ground	-0.6V to (V + 0.5V)
All output voltages with respect to ground	-0.6V to (V _{CC} + 0.5V)

*Notice: Stresses beyond those listed under “Absolute Maximum Ratings” may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

8.2 DC and AC Operating Range

Parameter	AT25XE321D
Operating Temperature (Case)	-40 °C to 85 °C
V _{CC} Power Supply	1.65V to 3.6V

8.3 DC Characteristics

Symbol	Parameter	Condition	1.65V to 3.6V			Units
			Min	Typ ⁽¹⁾	Max	
I _{UDPD} ⁽²⁾	Ultra-Deep Power-Down Current	$\overline{CS} = V_{CC}$. All other inputs at 0V or V _{CC}		5 - 7	250	nA
I _{DPD}	Deep Power-Down Current	$\overline{CS}, \overline{RESET}, \overline{WP} = V_{CC}$. All other inputs at 0V or V _{CC}		6	13	μA
I _{SB} ⁽³⁾⁽⁴⁾	Standby Current	$\overline{CS}, \overline{RESET}, \overline{WP} = V_{CC}$. All other inputs at 0V or V _{CC}		24	50	μA
I _{CC1} ⁽⁵⁾	SPI (33 MHz)	I _{OUT} = 0mA		5.1	6.9	mA
	SPI (104 MHz)	I _{OUT} = 0mA		7.6	12	mA
	Dual (104 MHz)	I _{OUT} = 0mA		11.0	12.4	mA
	Quad (104 MHz)	I _{OUT} = 0mA		11.8	14.6	mA
I _{CC3} ⁽⁶⁾	Active Current, Program Operation	$\overline{CS} = V_{CC}$		8.6	11	mA
I _{CC4}	Active Current, Erase Operation	$\overline{CS} = V_{CC}$		9.3	12	mA
I _{LI} ⁽⁷⁾	Input Load Current	All inputs at CMOS levels			±2	μA
I _{LO}	Output Leakage Current	All inputs at CMOS levels			±2	μA

8.3 DC Characteristics (continued)

Symbol	Parameter	Condition	1.65V to 3.6V			Units
			Min	Typ ⁽¹⁾	Max	
V _{IL}	Input Low Voltage				V _{CC} x 0.2	V
V _{IH}	Input High Voltage		V _{CC} x 0.8			V
V _{OL}	Output Low Voltage	I _{OL} = 100 μA			0.2	V
V _{OH}	Output High Voltage	I _{OH} = -100 μA	V _{CC} - 0.2			V

1. Typical values measured at 1.8V @ 25 °C for the 1.65V to 3.6V range.
2. I_{UPD} value is estimated. Not 100% tested.
3. During continuous read mode (0-4-4), I_{SB} may exceed maximum limit.
4. After >50,000 program/erase cycles, I_{SB} may exceed maximum limit.
5. I_{CC1} values are measured at Cload of ~50pF. The "No Load" (SO = open) values are estimated to be 10 - 20% lower.
6. Checkerboard pattern.
7. \overline{WP} (IO₂) and $\overline{HOLD/RESET}$ (IO₃) pins have an internal pull-up resistor. It's input load current is +2 / -30 μA.

8.4 AC Characteristics - Maximum Clock Frequencies

Symbol	Parameter	1.65V to 3.6V			Units
		Min	Typ	Max	
f _{SCK} ⁽¹⁾	Maximum clock frequency for all operations (except 03h command)			104	MHz
f _{RDLF}	Maximum clock frequency for 03h command (Read Array – Low Frequency)			40	MHz

1. When continuous read mode (0-4-4) is disabled, the maximum frequency of the EBh/E7h command is 85 MHz.

8.5 AC Characteristics – All Other Parameters

Symbol ⁽¹⁾	Parameter	1.65V to 3.6V			Units
		Min	Typ	Max	
t _{CLKH}	SCK High Time	4.5			ns
t _{CLKL}	SCK Low Time	4.5			ns
t _{CLKR}	Clock Rise Time, Peak-to-Peak (Slew Rate)	0.75			V/ns
t _{CLKF}	Clock Fall Time, Peak-to-Peak (Slew Rate)	0.75			V/ns
t _{CSH}	Minimum \overline{CS} High Time	35			ns
t _{CSLS}	\overline{CS} Low Setup Time (relative to clock)	6			ns
t _{CSLH}	\overline{CS} Low Hold Time (relative to clock)	6			ns
t _{CSHS}	\overline{CS} High Setup Time (relative to clock)	6			ns
t _{CSHH}	\overline{CS} High Hold Time (relative to clock)	6			ns

8.5 AC Characteristics – All Other Parameters (continued)

Symbol ⁽¹⁾	Parameter	1.65V to 3.6V			Units
		Min	Typ	Max	
t _{DS}	Data In Setup Time	2			ns
t _{DH}	Data In Hold Time	1			ns
t _{DIS}	Output Disable Time			8	ns
t _V	Output Valid Time			8	ns
t _{OH}	Output Hold Time	0			ns
t _{HLS}	$\overline{\text{HOLD}}$ Low Setup Time (relative to clock)	6			ns
t _{HLH}	$\overline{\text{HOLD}}$ Low Hold Time (relative to clock)	6			ns
t _{HHS}	$\overline{\text{HOLD}}$ High Setup Time (relative to clock)	6			ns
t _{HHH}	$\overline{\text{HOLD}}$ High Hold Time (relative to clock)	6			ns
t _{HLQZ}	$\overline{\text{HOLD}}$ Low to Output High-Z			7	ns
t _{HHQX}	$\overline{\text{HOLD}}$ High to Output Low-Z			7	ns
t _{WPS}	Write Protect Setup Time	20			ns
t _{WPH}	Write Protect Hold Time	100			ns
t _{EDPD}	$\overline{\text{CS}}$ High to Deep Power-Down			3	μs
t _{EU DPD}	$\overline{\text{CS}}$ High to Ultra Deep Power-Down			3	μs
t _{SWSTOP}	Resume from Terminate Command Time			50	μs
t _{SWRST}	Resume from Software Reset Time			260	μs
t _{RUDPD} ⁽²⁾	Resume form Ultra Deep Power-Down Time		160	260	μs
t _{RDPD}	Resume from Deep Power-Down Time			35	μs

1. Not 100% tested (value guaranteed by design and characterization).

2. The maximum spec is valid for UDPD hold time (duration of Ultra-Deep Power-Down state) of >400ms. For the shorter UDPD hold times, T_{RUDPD} may reach 1200 μs under some conditions.

8.6 Program and Erase Characteristics

Symbol	Parameter	1.65V - 3.6V			Units
		Min	Typ ⁽¹⁾	Max ⁽²⁾	
t _{RWM}	Read-Modify-Write Time		50	200	ms
t _{PP} ⁽³⁾	Page Program Time (256 Bytes)		1.5	8	ms
t _{BP} ⁽⁴⁾	Byte Program Time		22		μs
t _{PE}	Page Erase Time		11	40	ms

8.6 Program and Erase Characteristics (continued)

Symbol	Parameter	1.65V - 3.6V			Units
		Min	Typ ⁽¹⁾	Max ⁽²⁾	
t _{BLKE}	Block Erase Time	4 KBytes	66	115	ms
		32 KBytes	515	800	ms
		64 KBytes	800	1600	ms
t _{CHPE}	Chip Erase Time (32M density)		65		sec
t _{SUS}	Suspend Time (Program)			50	μs
	Suspend Time (Erase)			50	μs
t _{RES}	Resume Time (Program)		8	10	μs
	Resume Time (Erase)		8	10	μs
t _{OTPP}	OTP Security Register Program Time (<= 10K)		5	6	ms
t _{WRSR}	Write Status Register Time		13	37	ms

1. Typical values measured at 25 °C, 1.8V.
2. Unless otherwise specified, maximum is worst case measurement at cycling conditions after 100K cycles.
3. To preserve the data integrity of a sector, each page within a sector must be updated/rewritten at least once every 50,000 program/erase cycles.
4. Program time after the first byte varies.

8.7 Power On Timing

When power is first applied to the device, or when recovering from a reset condition, the output pin (SO) will be in a high impedance state, and a high-to-low transition on the \overline{CS} pin is required to start a valid instruction. The SPI mode (Mode 3 or Mode 0) is automatically selected on every falling edge of \overline{CS} by sampling the inactive clock state.

As the device initializes, there will be a transient current demand. The system needs to be capable of providing this current to ensure correct initialization. During power-up, the device must not be accessed for at least the minimum t_{VCSL} time after the supply voltage reaches the minimum VCC level (VCC min). While the device is being powered-up, the internal Power-On Reset (POR) circuitry keeps the device in a reset mode until the supply voltage rises above the minimum VCC. During this time, all operations are disabled and the device will not respond to any commands. (the t_{VCSL} time is measured from when VCC reaches VCC min.)

If Power-On-Reset (POR) has not been properly completed by the end of t_{VCSL} , the execution of a JEDEC Reset sequence restarts the POR process. This ensures the device can complete the POR sequence, even if some aspect of system Power-On voltage ramp-up causes the POR to not initiate or complete correctly.

Figure 8-11 shows the AC timing during power-up.

Figure 8-11. AC Timing During Device Power Up

Table 8-27. Power On Timing Requirements

Symbol	Parameter	1.65V - 3.6V			Units
		Min	Typ	Max	
t_{VCSL}	Minimum V _{CC} to full operation permitted			260	μs
t_{VR}	V _{CC} rise time (from 0V to VCCmin)		1	30000	μs/V
t_{PWD}	V _{CC} brown-out low time	300			μs
V_{PWDMAX}	Maximum V _{CC} brown-out			0.2	V

Figure 8-12 shows the AC power-up timing after a brown-out condition.

9. Ordering Information

9.1 Ordering Code Detail

Table 9-1. Valid Ordering Code Table

Valid Part Number	Mechanical Drawing	Description	Lead Finish	Operating Voltage	Temperature Range
AT25XE321D-SSH-N-B AT25XE321D-SSH-N-T	8S1	8-lead, 0.150" Narrow Plastic Gull Wing Small Outline Package (JEDEC SOIC)	NiPdAu	1.65V to 3.6V	Industrial (-40°C to +85°C)
AT25XE321D-SH-N-B AT25XE321D-SH-N-T	8S2	8-lead, 0.208" Wide Plastic Gull Wing Small Outline Package (EIAJ SOIC)			
AT25XE321D-MH-N-Y AT25XE321D-MH-N-T	8MA1	8-pad, 5 x 6 x 0.6mm, Thermally Enhanced Plastic Ultra Thin Dual Flat No Lead Package (UDFN)	NiPdAu	1.65V to 3.6V	Industrial (-40°C to +85°C)
AT25XE321D-UUN-T					

1. Contact Adesto for WLCSP package availability.

10. Packaging Information

The AT25XE321D device supports the following package types:

- 8S1, 8-lead 0.150 narrow body JEDEC SOIC
- 8S2, 8-lead 0.208 wide body EIAJ
- 8MA1, 5 x 6 x 0.6 mm UDFN
- 12-WLCSP, 12-ball 3 x 2 x 3 array WLCSP

Each of these packages is described in the following subsections.

10.1 8S1 — JEDEC SOIC

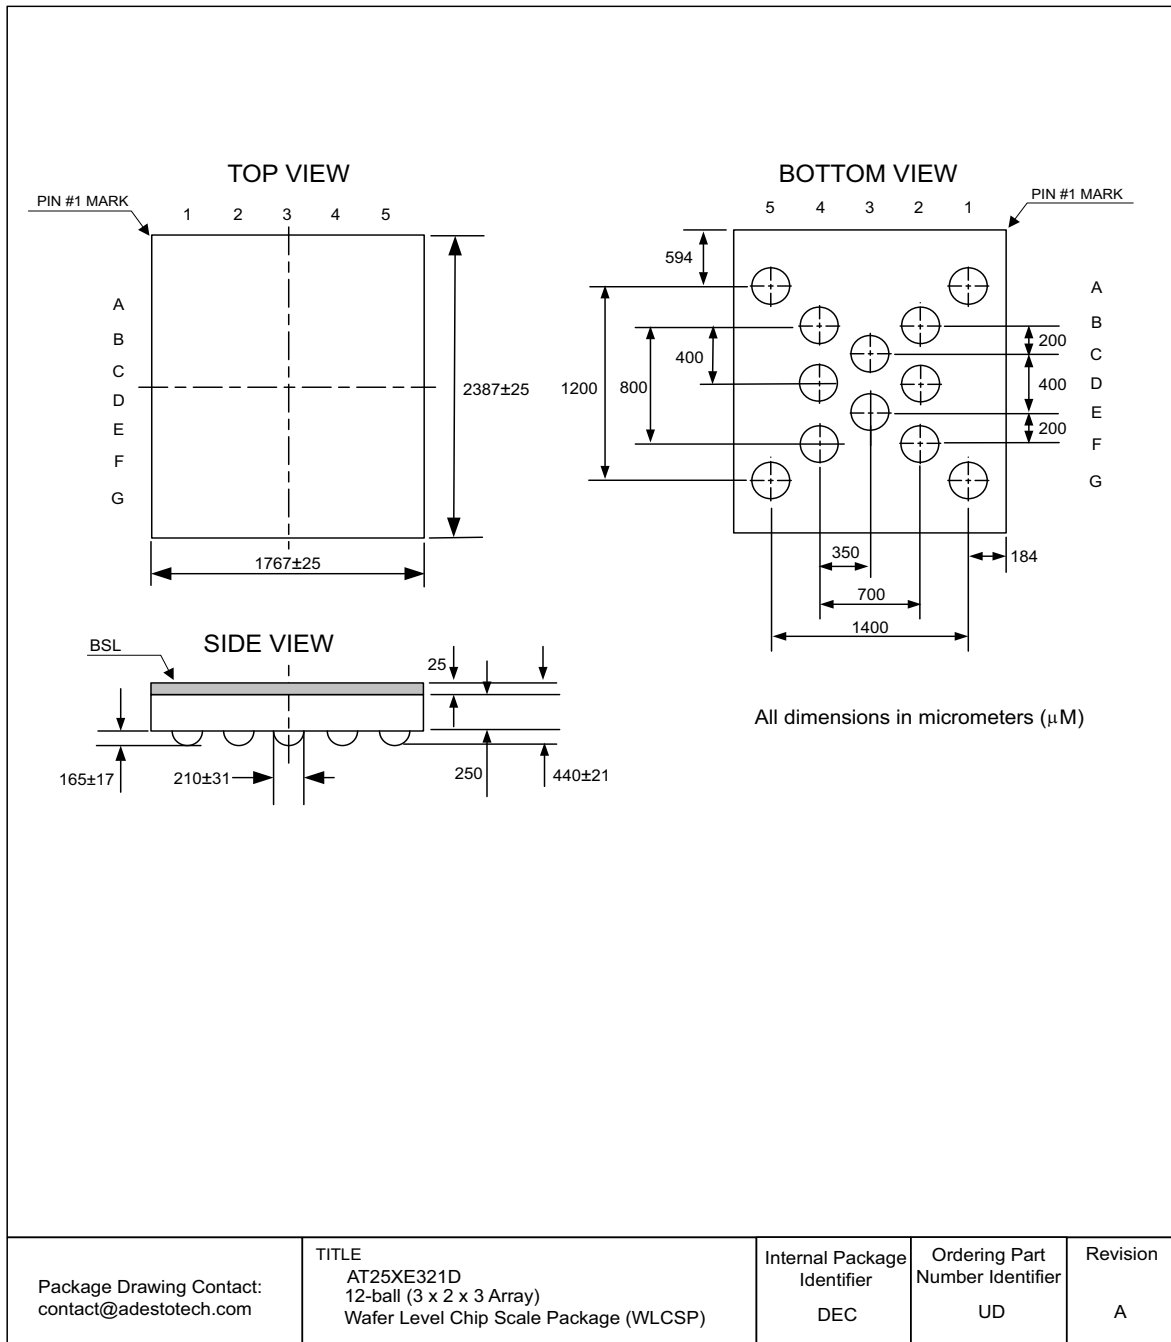

10.2 8S2 — 8-lead EIAJ SOIC

10.3 8MA1 — 5 x 6 UDFN

10.4 12WLCSP — 12-ball WLCSP

11. Glossary

The following glossary defines the terms and abbreviations used in this document.

Term/Abbreviation	Definition
EEPROM	Electrically Erasable/Programmable Read Only Memory
JEDEC	Joint Electron Device Engineering Council
Kb	Kilobit
KB	Kilobyte
LSB	Least significant bit
Mb	Megabit
MB	Megabyte
MCU	Microcontroller Unit
MSB	Most significant bit
OTP	One Time Programmable
RMW	Read-Modify-Write
SCK	Serial Clock
SFDP	Serial Flash Discoverable Parameters
SI	Serial In
SO	Serial Out
SOIC	Small Outline Integrated Circuit
SPI	Serial Peripheral Interface
SR	Status Register
SRAM	Static Random Access Memory
UDFN	Ultra-Dual Flat No Lead
WLCSP	Wafer Level Chip Scale Package
WP	Write Protect
XiP	Execute-in-Place
xxh	8-bit hexadecimal value, such as 03h. All commands are defined in this manner.
xxxxh	16-bit hexadecimal value. For example, 1010h.
x'bx....x	Binary value. The number of binary bits is indicated by the first digit. For example, 4'b0110 is a 4-bit binary value.

12. Revision History

Document Revision	Date	Change History
A	3/2018	Initial release of Fusion 32 Mbit data sheet.
B	11/2018	<p>Updated text for steps 1, 2, and 3 in Section 5.4, Power Down Considerations. Updated encoding of the DRV[1:0] bits in Table 6-6, Status Register 3.</p> <p>Added Resume from Ultra-Deep Power Down mode (ABh) instruction to Table 7-10, Command Listing.</p> <p>Updated text in Section 7.33, Deep Power Down.</p> <p>Updated text in Section 7.34, Resume from Deep Power Down.</p> <p>Updated text in Section 7.35, Ultra-Deep Power Down, to include mention of the ABh command as a way to Resume from Ultra-Deep Power Down.</p> <p>Updated Section 7.39.3, Transfer Sequence, for the Quad Read Manufacturer/Device ID command in Section 7.39.</p> <p>Changed t_{XUDPD} timing parameter acronym to t_{UDPD} in Section 8.5, AC Characteristics.</p> <p>Changed t_{RDPD} timing parameter acronym to t_{DPD} in Section 8.5, AC Characteristics and updated timing parameter.</p> <p>Added footnote to 12-WLCSP package in the tables of Section 9.1, Ordering Code Detail.</p> <p>Updated dimension E of 8S2 package in Section 10.2.</p> <p>Added Section 11, Glossary.</p> <p>Removed R-M-W flow diagram in Section 5.11.</p> <p>Updated memory protection tables in Section 5.3.1.</p>
C	7/2019	<p>Conversion to new Adesto template.</p> <p>Changed device revision from B to D.</p> <p>Updated Section 7.44, Read SFDP (5Ah).</p> <p>Updated WLCSP package information from 8-ball to 12-ball throughout document.</p> <p>Updated 12-ball WLCSP package drawing in Section 2.</p>
D	1/2020	<p>Updated all values in Section 8-3, DC Characteristics.</p> <p>Updated the f_{SCK} and f_{RDLF} frequencies in Section 8.4.</p> <p>Updated all timings in Section 8.5, AC Characteristics.</p> <p>Updated all timings in Section 8.6, Program and Erase Characteristics.</p> <p>Updated description of DRV[1:0] bits in Section 6.5, Status Register 3.</p> <p>Added notes 1 - 4 to Table 5-4, Device Block Protection Map (CMPRT = 1).</p> <p>Added paragraph at end of Section 8.7, Power-on Timing.</p> <p>Changed Bits 5:4 to reserved in Section 6.6, Status Register 4.</p> <p>Removed references to the Page Error (PE) and Erase Error (EE) bits and associated functionality throughout document.</p> <p>Added footnote to Table 6-6, Status Register 3 Format.</p> <p>Changed status from ADVANCED to PRELIMINARY.</p>
E	2/2020	<p>Updated t_{BP} byte program timing in Section 8.6, Program and Erase Characteristics.</p> <p>Added footnotes 3 and 4 to Section 8.6.</p>
