

## Introduction

The Zynq®-7000 SoCs are available in -3, -2, -2LI, -1, and -1LQ speed grades, with -3 having the highest performance. The -2LI devices operate at programmable logic (PL)  $V_{CCINT}/V_{CCBRAM} = 0.95V$  and are screened for lower maximum static power. The speed specification of a -2LI device is the same as that of a -2 device. The -1LQ devices operate at the same voltage and speed as the -1Q devices and are screened for lower power. Zynq-7000 device DC and AC characteristics are specified in commercial, extended, industrial, and expanded (Q-temp) temperature ranges. Except the operating temperature range or unless otherwise noted, all the DC and AC electrical parameters are the same for a particular speed grade (that is, the timing characteristics of a -1 speed grade industrial device are the same as for a -1 speed grade commercial device). However, only selected speed grades and/or devices are available in the commercial, extended, or industrial temperature ranges.

All supply voltage and junction temperature specifications are representative of worst-case conditions. The parameters included are common to popular designs and typical applications.

The available device/package combinations are outlined in:

**Notes:**

- All voltages are relative to ground. The PL and PS share a common ground.
- For the design of the power distribution system consult the *Zynq-7000 SoC PCB Design Guide* ([UG933](#)).
- When the processor cores operate F<sub>CPU\_6X4X\_621\_MAX</sub> at 1 GHz (-3E speed grade) or when the DDR interface operates at 1333 Mb/s, the V<sub>CCPINT</sub> minimum is 0.97V and the V<sub>CCPINT</sub> maximum is 1.03V.
- Applies to both MIO supply banks V<sub>CCO\_MIO0</sub> and V<sub>CCO\_MIO1</sub>.
- The lower absolute voltage specification always applies.
- V<sub>CCINT</sub> and V<sub>CCBRAM</sub> should be connected to the same supply.
- Configuration data is retained even if V<sub>CCO</sub> drops to 0V.
- Includes V<sub>CCO</sub> of 1.2V, 1.35V, 1.5V, 1.8V, 2.5V (HR I/O only), and 3.3V (HR I/O only) at ±5%.
- For more information, refer to the V<sub>CCAUX\_IO</sub> section of the *7 Series FPGAs SelectIO Resources User Guide* ([UG471](#)) or the *Zynq-7000 SoC Technical Reference Manual* ([UG585](#)).
- See [Table 12](#) for TMD5\_33 specifications.
- A total of 200 mA per PS or PL bank should not be exceeded.
- V<sub>CCBATT</sub> is required only when using bitstream encryption. If battery is not used, connect V<sub>CCBATT</sub> to either ground or V<sub>CCAUX</sub>.
- Each voltage listed requires the filter circuit described in the *7 Series FPGAs GTX/GTH Transceivers User Guide* ([UG476](#)).
- For data rates ≤ 10.3125 Gb/s, V<sub>MGTAVCC</sub> should be 1.0V ±3% for lower power consumption.
- For lower power consumption, V<sub>MGTAVCC</sub> should be 1.0V ±3% over the entire CPLL frequency range.

**Notes:**

1. Typical values are specified at nominal voltage, 85°C junction temperatures (T<sub>j</sub>) with single-ended SelectIO resources.
2. Typical values are for blank configured devices with no output current loads, no active input pull-up resistors, all I/O pins are 3-state and floating.
3. Use the Xilinx Power Estimator (XPE) spreadsheet tool (download at <http://www.xilinx.com/power>) to estimate static power consumption for conditions other than those specified.

## PS Power-On/Off Power Supply Sequencing

The recommended power-on sequence is  $V_{CCPINT}$ , then  $V_{CCPAUX}$  and  $V_{CCPLL}$  together, then the PS  $V_{CCO}$  supplies ( $V_{CCO\_MIO0}$ ,  $V_{CCO\_MIO1}$ , and  $V_{CCO\_DDR}$ ) to achieve minimum current draw and ensure that the I/Os are 3-stated at power-on. The PS\_POR\_B input is required to be asserted to GND during the power-on sequence until  $V_{CCPINT}$ ,  $V_{CCPAUX}$  and  $V_{CCO\_MIO0}$  have reached minimum operating levels to ensure PS eFUSE integrity. For additional information about PS\_POR\_B timing requirements refer to [Resets](#).

The recommended power-off sequence is the reverse of the power-on sequence. If  $V_{CCPAUX}$ ,  $V_{CCPLL}$ , and the PS  $V_{CCO}$  supplies ( $V_{CCO\_MIO0}$ ,  $V_{CCO\_MIO1}$ , and  $V_{CCO\_DDR}$ ) have the same recommended voltage levels, then they can be powered by the same supply and ramped simultaneously. Xilinx recommends powering  $V_{CCPLL}$  with the same supply as  $V_{CCPAUX}$ , with an optional ferrite bead filter. Before  $V_{CCPINT}$  reaches 0.80V at least one of the four following conditions is required during the power-off stage: the PS\_POR\_B input is asserted to GND, the reference clock to the PS\_CLK input is disabled,  $V_{CCPAUX}$  is lower than 0.70V, or  $V_{CCO\_MIO0}$  is lower than 0.90V. The condition must be held until  $V_{CCPINT}$  reaches 0.40V to ensure PS eFUSE integrity.

For  $V_{CCO\_MIO0}$  and  $V_{CCO\_MIO1}$  voltages of 3.3V:

- The voltage difference between  $V_{CCO\_MIO0}/V_{CCO\_MIO1}$  and  $V_{CCPAUX}$  must not exceed 2.625V for longer than  $T_{VCCO2VCCAUX}$  for each power-on/off cycle to maintain device reliability levels.
- The  $T_{VCCO2VCCAUX}$  time can be allocated in any percentage between the power-on and power-off ramps.

## PL Power-On/Off Power Supply Sequencing

The recommended power-on sequence for the PL is  $V_{CCINT}$ ,  $V_{CCBRAM}$ ,  $V_{CCAUX}$ ,  $V_{CCAUX\_IO}$ , and  $V_{CCO}$  to achieve minimum current draw and ensure that the I/Os are 3-stated at power-on. The recommended power-off sequence is the reverse of the power-on sequence. If  $V_{CCINT}$  and  $V_{CCBRAM}$  have the same recommended voltage levels then both can be powered by the same supply and ramped simultaneously. If  $V_{CCAUX}$ ,  $V_{CCAUX\_IO}$ , and  $V_{CCO}$  have the same recommended voltage levels then they can be powered by the same supply and ramped simultaneously.

For  $V_{CCO}$  voltages of 3.3V in HR I/O banks and configuration bank 0:

- The voltage difference between  $V_{CCO}$  and  $V_{CCAUX}$  must not exceed 2.625V for longer than  $T_{VCCO2VCCAUX}$  for each power-on/off cycle to maintain device reliability levels.
- The  $T_{VCCO2VCCAUX}$  time can be allocated in any percentage between the power-on and power-off ramps.

The recommended power-on sequence to achieve minimum current draw for the GTX transceivers is  $V_{CCINT}$ ,  $V_{MGTAVCC}$ ,  $V_{MGTAVTT}$  OR  $V_{MGTAVCC}$ ,  $V_{CCINT}$ ,  $V_{MGTAVTT}$ . There is no recommended sequencing for  $V_{MGTAVCCAUX}$ . Both  $V_{MGTAVCC}$  and  $V_{CCINT}$  can be ramped simultaneously. The recommended power-off sequence is the reverse of the power-on sequence to achieve minimum current draw.

If these recommended sequences are not met, current drawn from  $V_{MGTAVTT}$  can be higher than specifications during power-up and power-down.

- When  $V_{MGTAVTT}$  is powered before  $V_{MGTAVCC}$  and  $V_{MGTAVTT} - V_{MGTAVCC} > 150$  mV and  $V_{MGTAVCC} < 0.7$ V, the  $V_{MGTAVTT}$  current draw can increase by 460 mA per transceiver during  $V_{MGTAVCC}$  ramp up. The duration of the current draw can be up to  $0.3 \times T_{MGTAVCC}$  (ramp time from GND to 90% of  $V_{MGTAVCC}$ ). The reverse is true for power-down.
- When  $V_{MGTAVTT}$  is powered before  $V_{CCINT}$  and  $V_{MGTAVTT} - V_{CCINT} > 150$  mV and  $V_{CCINT} < 0.7$ V, the  $V_{MGTAVTT}$  current draw can increase by 50 mA per transceiver during  $V_{CCINT}$  ramp up. The duration of the current draw can be up to  $0.3 \times T_{VCCINT}$  (ramp time from GND to 90% of  $V_{CCINT}$ ). The reverse is true for power-down.

There is no recommended sequence for supplies not shown.

## PS—PL Power Sequencing

The PS and PL power supplies are fully independent. PS power supplies ( $V_{CCPINT}$ ,  $V_{CCPAUX}$ ,  $V_{CCPLL}$ ,  $V_{CCO\_DDR}$ ,  $V_{CCO\_MIO0}$ , and  $V_{CCO\_MIO1}$ ) can be powered before or after any PL power supplies. The PS and PL power regions are isolated to prevent damage.

## Power Supply Requirements

Table 7 shows the minimum current, in addition to  $I_{CCQ}$ , that is required by Zynq-7000 devices for proper power-on and configuration. If the current minimums shown in Table 6 and Table 7 are met, the device powers on after all five supplies have passed through their power-on reset threshold voltages. The Zynq-7000 device must not be configured until after  $V_{CCINT}$  is applied. Once initialized and configured, use the Xilinx Power Estimator (XPE) spreadsheet tool (download at [www.xilinx.com/power](http://www.xilinx.com/power)) to estimate current drain on these supplies.

## DC Input and Output Levels

Values for  $V_{IL}$  and  $V_{IH}$  are recommended input voltages. Values for  $I_{OL}$  and  $I_{OH}$  are guaranteed over the recommended operating conditions at the  $V_{OL}$  and  $V_{OH}$  test points. Only selected standards are tested. These are chosen to ensure that all standards meet their specifications. The selected standards are tested at a minimum  $V_{CCO}$  with the respective  $V_{OL}$  and  $V_{OH}$  voltage levels shown. Other standards are sample tested.

## AC Switching Characteristics

All values represented in this data sheet are based on the speed specifications in the ISE® Design Suite 14.7 and Vivado® Design Suite 2015.4 as outlined in [Table 16](#).

Table 16: Zynq-7000 SoC Speed Specification Version By Device

ISE 14.7	Vivado 2015.4	Device
1.08	1.11	XC7Z030 and XC7Z045
N/A	1.11	XC7Z035 and XC7Z100
N/A	1.09	XA7Z030
1.06	1.10	XQ7Z030 and XQ7Z045
N/A	1.10	XQ7Z100

Switching characteristics are specified on a per-speed-grade basis and can be designated as Advance, Preliminary, or Production. Each designation is defined as follows:

### Advance Product Specification

These specifications are based on simulations only and are typically available soon after device design specifications are frozen. Although speed grades with this designation are considered relatively stable and conservative, some under-reporting might still occur.

### Preliminary Product Specification

These specifications are based on complete ES (engineering sample) silicon characterization. Devices and speed grades with this designation are intended to give a better indication of the expected performance of production silicon. The probability of under-reporting delays is greatly reduced as compared to Advance data.

### Production Product Specification

These specifications are released once enough production silicon of a particular device family member has been characterized to provide full correlation between specifications and devices over numerous production lots. There is no under-reporting of delays, and customers receive formal notification of any subsequent changes. Typically, the slowest speed grades transition to Production before faster speed grades.

## Testing of AC Switching Characteristics

Internal timing parameters are derived from measuring internal test patterns. All AC switching characteristics are representative of worst-case supply voltage and junction temperature conditions.

For more specific, more precise, and worst-case guaranteed data, use the values reported by the static timing analyzer and back-annotate to the simulation net list. Unless otherwise noted, values apply to all Zynq-7000 devices.

## Speed Grade Designations

Since individual family members are produced at different times, the migration from one category to another depends completely on the status of the fabrication process for each device. [Table 17](#) correlates the current status of each Zynq-7000 device on a per speed grade basis.

Table 17: Zynq-7000 Device Speed Grade Designations

XQ7Z045			-2I, -2LI, -1I, -1Q, -1LQ
XQ7Z100			-2I, -2LI, -1I

## Production Silicon and Software Status

In some cases, a particular family member (and speed grade) is released to production before a speed specification is released with the correct label (Advance, Preliminary, Production). Any labeling discrepancies are corrected in subsequent speed specification releases.

Table 18 lists the production released Zynq-7000 device, speed grade, and the minimum corresponding supported speed specification version and software revisions. The software and speed specifications listed are the minimum releases required for production. All subsequent releases of software and speed specifications are valid.

## Selecting the Correct Speed Grade and Voltage in the Vivado Tools

It is important to select the correct device speed grade and voltage in the Vivado tools for the device that you are selecting.

To select the -3, -2, or -1 (PL 1.0V) speed specifications in the Vivado tools, select the **Zynq-7000**, **XA Zynq-7000**, or **Defense Grade Zynq-7000** sub-family, and then select the part name that is the device name followed by the package name followed by the speed grade. For example, select the **xc7z030ifbg676-3** part name for the XC7Z030 device in the FBG676 package and -3 speed grade.

To select the -2LI (PL 0.95V) speed specifications in the Vivado tools, select the **Zynq-7000** sub-family and then select the part name that is the device name followed by an *i* followed by the package name followed by the speed grade. For example, select the **xc7z030ifbg676-2L** part name for the XC7Z030 device in the FBG676 package and -2LI (PL 0.95V) speed grade. The -2LI (PL 0.95V) speed specifications are not supported in the ISE tools.

A similar part naming convention applies to the speed specifications selection in the ISE tools for supported devices. See Table 18 for the subset of Zynq-7000 devices supported in the ISE tools.

Figure 1 shows the timing relationship between PS\_POR\_B and the last power supply ramp (V<sub>CCINT</sub>, V<sub>CCBRAM</sub>, V<sub>CCAUX</sub>, or V<sub>CCO</sub> in bank 0). T<sub>SLW</sub> minimum and maximum parameters define the beginning and end, respectively, of the secure lockdown window relative to the last PL power supply reaching 250 mV. The PS\_POR\_B must not be deasserted within the secure lockdown window.

[Table 53](#) provides the maximum data rates for applicable memory standards using the Zynq-7000 SoC memory PHY. The final performance of the memory interface is determined through a complete design implemented in the Vivado or ISE Design Suite, following guidelines in the *Zynq-7000 SoC and 7 Series Devices Memory Interface Solutions User Guide (UG586)*.

1. V<sub>REF</sub> tracking is required. For more information, see the *Zynq-7000 SoC and 7 Series Devices Memory Interface Solutions User Guide* (UG586).
2. When using the internal V<sub>REF</sub>, the maximum data rate is 800 Mb/s (400 MHz).
3. For designs using 1866 Mb/s components, contact [Xilinx Technical Support](#).
4. The maximum QDRII+ performance specifications are for burst-length 4 (BL = 4) implementations. Burst length 2 (BL = 2) implementations are limited to 333 MHz for all speed grades and I/O bank types.

## PL Switching Characteristics

### IOB Pad Input/Output/3-State

Table 55 (high-range IOB (HR)) and Table 56 (high-performance IOB (HP)) summarizes the values of standard-specific data input delay adjustments, output delays terminating at pads (based on standard) and 3-state delays.

- $T_{IOPI}$  is described as the delay from IOB pad through the input buffer to the I-pin of an IOB pad. The delay varies depending on the capability of the SelectIO input buffer.
- $T_{IOOP}$  is described as the delay from the O pin to the IOB pad through the output buffer of an IOB pad. The delay varies depending on the capability of the SelectIO output buffer.
- $T_{IOTP}$  is described as the delay from the T pin to the IOB pad through the output buffer of an IOB pad, when 3-state is disabled. The delay varies depending on the SelectIO capability of the output buffer. In HP I/O banks, the internal DCI termination turn-on time is always faster than  $T_{IOTP}$  when the DCITERMDISABLE pin is used. In HR I/O banks, the IN\_TERM termination turn-on time is always faster than  $T_{IOTP}$  when the INTERMDISABLE pin is used.

Table 57 specifies the values of  $T_{IOTPHZ}$  and  $T_{IOIBUFDISABLE}$ .  $T_{IOTPHZ}$  is described as the delay from the T pin to the IOB pad through the output buffer of an IOB pad, when 3-state is enabled (i.e., a high impedance state).  $T_{IOIBUFDISABLE}$  is described as the IOB delay from IBUFDISABLE to O output. In HP I/O banks, the internal DCI termination turn-off time is always faster than  $T_{IOTPHZ}$  when the DCITERMDISABLE pin is used. In HR I/O banks, the internal IN\_TERM termination turn-off time is always faster than  $T_{IOTPHZ}$  when the INTERMDISABLE pin is used.

**Notes:**

1. The input delay measurement methodology parameters for LVDCI are the same for LVCMOS standards of the same voltage. Input delay measurement methodology parameters for HSLVDCI are the same as for HSTL\_II standards of the same voltage. Parameters for all other DCI standards are the same for the corresponding non-DCI standards.
2. Input waveform switches between  $V_L$  and  $V_H$ .
3. Measurements are made at typical, minimum, and maximum  $V_{REF}$  values. Reported delays reflect worst case of these measurements.  $V_{REF}$  values listed are typical.
4. Input voltage level from which measurement starts.
5. This is an input voltage reference that bears no relation to the  $V_{REF} / V_{MEAS}$  parameters found in IBIS models and/or noted in Figure 18.
6. The value given is the differential input voltage.

**Output Delay Measurements**

Output delays are measured with short output traces. Standard termination was used for all testing. The propagation delay of the trace is characterized separately and subtracted from the final measurement, and is therefore not included in the generalized test setups shown in Figure 18 and Figure 19.

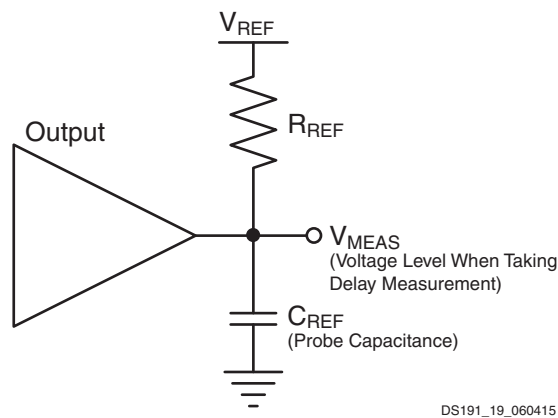

Figure 18: Single-Ended Test Setup

Figure 19: Differential Test Setup

Parameters  $V_{REF}$ ,  $R_{REF}$ ,  $C_{REF}$ , and  $V_{MEAS}$  fully describe the test conditions for each I/O standard. The most accurate prediction of propagation delay in any given application can be obtained through IBIS simulation, using this method:

1. Simulate the output driver of choice into the generalized test setup using values from Table 59.
2. Record the time to  $V_{MEAS}$ .
3. Simulate the output driver of choice into the actual PCB trace and load using the appropriate IBIS model or capacitance value to represent the load.
4. Record the time to  $V_{MEAS}$ .

5. Compare the results of [step 2](#) and [step 4](#). The increase or decrease in delay yields the actual propagation delay of the PCB trace.

2.  $T_{RCKO\_DOR}$  includes  $T_{RCKO\_DOW}$ ,  $T_{RCKO\_DOPR}$ , and  $T_{RCKO\_DOPW}$  as well as the B port equivalent timing parameters.
3. These parameters also apply to synchronous FIFO with  $DO\_REG = 0$ .
4.  $T_{RCKO\_DO}$  includes  $T_{RCKO\_DOP}$  as well as the B port equivalent timing parameters.
5. These parameters also apply to multirate (asynchronous) and synchronous FIFO with  $DO\_REG = 1$ .
6.  $T_{RCKO\_FLAGS}$  includes the following parameters:  $T_{RCKO\_AEMPTY}$ ,  $T_{RCKO\_AFULL}$ ,  $T_{RCKO\_EMPTY}$ ,  $T_{RCKO\_FULL}$ ,  $T_{RCKO\_RDERR}$ ,  $T_{RCKO\_WRERR}$ .

8. The ADDR setup and hold must be met when EN is asserted (even when WE is deasserted). Otherwise, block RAM data corruption is possible.
9. These parameters include both A and B inputs as well as the parity inputs of A and B.
10.  $T_{RCO\_FLAGS}$  includes the following flags: AEMPTY, AFULL, EMPTY, FULL, RDERR, WRERR, RDCOUNT, and WRCOUNT.
11. RDEN and WREN must be held Low prior to and during reset. The FIFO reset must be asserted for at least five positive clock edges of the slowest clock (WRCLK or RDCLK).

- $T_{BCCCK\_CE}$  and  $T_{BCCCK\_S}$  must be satisfied to assure glitch-free operation of the global clock when switching between clocks. These parameters do not apply to the BUFGMUX primitive that assures glitch-free operation. The other global clock setup and hold times are optional; only needing to be satisfied if device operation requires simulation matches on a cycle-for-cycle basis when switching between clocks.
- $T_{BCCCKO\_O}$  (BUFG delay from I0 to O) values are the same as  $T_{BCCCKO\_O}$  values.

Notes:

1. These parameters represent the worst-case duty-cycle distortion observable at the pins of the device using LVDS output buffers. For cases where other I/O standards are used, IBIS can be used to calculate any additional duty-cycle distortion that might be caused by asymmetrical rise/fall times.
2. The T<sub>CKSKEW</sub> value represents the worst-case clock-tree skew observable between sequential I/O elements. Significantly less clock-tree skew exists for I/O registers that are close to each other and fed by the same or adjacent clock-tree branches. Use the Xilinx Timing Analyzer tools to evaluate application specific clock skew.

Hold time is measured relative to the global clock input signal using the fastest process, lowest temperature, and highest voltage.
- IFF = Input flip-flop or latch.

Notes:

1. This parameter indicates the total sampling error of the PL DDR input registers, measured across voltage, temperature, and process. The characterization methodology uses the MMCM to capture the DDR input registers' edges of operation. These measurements include:
  - CLK0 MMCM jitter
  - MMCM accuracy (phase offset)
  - MMCM phase shift resolution
 These measurements do not include package or clock tree skew.
2. This parameter indicates the total sampling error of the PL DDR input registers, measured across voltage, temperature, and process. The characterization methodology uses the BUFIO clock network and IDELAY to capture the DDR input registers' edges of operation. These measurements do not include package or clock tree skew.

**Notes:**

- Offset and gain errors are removed by enabling the XADC automatic gain calibration feature. The values are specified for when this feature is enabled.
- Only specified for bitstream option XADCEnhancedLinearity = ON.
- See the ADC chapter in the *7 Series FPGAs and Zynq-7000 SoC XADC Dual 12-Bit 1 MSPS Analog-to-Digital Converter User Guide (UG480)* for a detailed description.
- See the Timing chapter in the *7 Series FPGAs and Zynq-7000 SoC XADC Dual 12-Bit 1 MSPS Analog-to-Digital Converter User Guide (UG480)* for a detailed description.
- Any variation in the reference voltage from the nominal V<sub>REFP</sub> = 1.25V and V<sub>REFN</sub> = 0V will result in a deviation from the ideal transfer function. This also impacts the accuracy of the internal sensor measurements (i.e., temperature and power supply). However, for external ratiometric type applications allowing reference to vary by ±4% is permitted.
