The **GPIODR** register is the open drain control register. Setting a bit in this register enables the open-drain configuration of the corresponding GPIO pad. When open-drain mode is enabled, the corresponding bit should also be set in the **GPIO Digital Enable (GPIODEN)** register (see page 773). Corresponding bits in the drive strength and slew rate control registers (**GPIODR2R**, **GPIODR4R**, **GPIODR8R**, and **GPIOSLR**) can be set to achieve the desired fall times. The GPIO acts as an input if the corresponding bit in the **GPIODIR** register is cleared. If open drain is selected while the GPIO is configured as an input, the GPIO will remain an input and the open-drain selection has no effect until the GPIO is changed to an output.

When using the I<sup>2</sup>C module, in addition to configuring the data pin to open drain, the **GPIO Alternate Function Select (GPIOAFSEL)** register bits for the I<sup>2</sup>C clock and data pins should be set (see examples in “Initialization and Configuration” on page 744).

**Note:** This register has no effect on port pins PL6 and PL7.

**Register 15: GPIO Pull-Up Select (GPIOPUR), offset 0x510**

The **GPIOPUR** register is the pull-up control register. When a bit is set, a weak pull-up resistor on the corresponding GPIO signal is enabled. Setting a bit in **GPIOPUR** automatically clears the corresponding bit in the **GPIO Pull-Down Select (GPIOPDR)** register (see page 770). Write access to this register is protected with the **GPIOCR** register. Bits in **GPIOCR** that are cleared prevent writes to the equivalent bit in this register.

**Important:** The table below shows special consideration GPIO pins. Most GPIO pins are configured as GPIOs and tri-stated by default (**GPIOAFSEL**=0, **GPIODEN**=0, **GPIOPDR**=0, **GPIOPUR**=0, and **GPIOCTL**=0). Special consideration pins may be programmed to a non-GPIO function or may have special commit controls out of reset. In addition, a Power-On-Reset ( $\overline{POR}$ ) returns these GPIO to their original special consideration state.

**Table 10-9. GPIO Pins With Special Considerations**

| GPIO Pins | Default Reset State | GPIOAFSEL | GPIODEN | GPIOPDR | GPIOPUR | GPIOCTL | GPIOCR |
|-----------|---------------------|-----------|---------|---------|---------|---------|--------|
| PC[3:0]   | JTAG/SWD            | 1         | 1       | 0       | 1       | 0x1     | 0      |
| PD[7]     | GPIO <sup>a</sup>   | 0         | 0       | 0       | 0       | 0x0     | 0      |
| PE[7]     | GPIO <sup>a</sup>   | 0         | 0       | 0       | 0       | 0x0     | 0      |

a. This pin is configured as a GPIO by default but is locked and can only be reprogrammed by unlocking the pin in the **GPIOLOCK** register and uncommitting it by setting the **GPIOCR** register.

The GPIO commit control registers provide a layer of protection against accidental programming of critical hardware signals including the GPIO pins that can function as JTAG/SWD signals and the **NMI** signal. The commit control process must be followed for these pins, even if they are programmed as alternate functions other than JTAG/SWD or **NMI**; see “Commit Control” on page 743.

**Note:** If the device fails initialization during reset, the hardware toggles the **TDO** output as an indication of failure. Thus, during board layout, designers should not designate the **TDO** pin as a GPIO in sensitive applications where the possibility of toggling could affect the design.

**Note:** The GPIO commit control registers provide a layer of protection against accidental programming of critical hardware peripherals. Protection is provided for the GPIO pins that can be used as the four JTAG/SWD pins and the **NMI** pin (see “Signal Tables” on page 1646 for pin numbers). Writes to protected bits of the **GPIO Alternate Function Select (GPIOAFSEL)** register (see page 762), **GPIO Pull Up Select (GPIOPUR)** register (see page 768), **GPIO Pull-Down Select (GPIOPDR)** register (see page 770), and **GPIO Digital Enable (GPIODEN)** register (see page 773) are not committed to storage unless the **GPIO Lock (GPIOLOCK)** register (see page 775) has been unlocked and the appropriate bits of the **GPIO Commit (GPIOCR)** register (see page 776) have been set.

## Value Description

0 The corresponding pin's weak pull-up resistor is disabled.

1 The corresponding pin's weak pull-up resistor is enabled.

Setting a bit in the **GPIOPDR** register clears the corresponding bit in the **GPIOPUR** register. The change is effective on the next clock cycle.

The reset value for this register is 0x0000.0000 for GPIO ports that are not listed in Table 10-1 on page 732.

**Register 16: GPIO Pull-Down Select (GPIOPDR), offset 0x514**

The **GPIOPDR** register is the pull-down control register. When a bit is set, a weak pull-down resistor on the corresponding GPIO signal is enabled. Setting a bit in **GPIOPDR** automatically clears the corresponding bit in the **GPIO Pull-Up Select (GPIOPUR)** register (see page 768).

**Important:** The table below shows special consideration GPIO pins. Most GPIO pins are configured as GPIOs and tri-stated by default (**GPIOAFSEL=0**, **GPIODEN=0**, **GPIOPDR=0**, **GPIOPUR=0**, and **GPIOCTL=0**). Special consideration pins may be programmed to a non-GPIO function or may have special commit controls out of reset. In addition, a Power-On-Reset ( $\overline{POR}$ ) returns these GPIO to their original special consideration state.

**Table 10-10. GPIO Pins With Special Considerations**

| GPIO Pins | Default Reset State | GPIOAFSEL | GPIODEN | GPIOPDR | GPIOPUR | GPIOCTL | GPIOCR |
|-----------|---------------------|-----------|---------|---------|---------|---------|--------|
| PC[3:0]   | JTAG/SWD            | 1         | 1       | 0       | 1       | 0x1     | 0      |
| PD[7]     | GPIO <sup>a</sup>   | 0         | 0       | 0       | 0       | 0x0     | 0      |
| PE[7]     | GPIO <sup>a</sup>   | 0         | 0       | 0       | 0       | 0x0     | 0      |

a. This pin is configured as a GPIO by default but is locked and can only be reprogrammed by unlocking the pin in the **GPIOLOCK** register and uncommitting it by setting the **GPIOCR** register.

The GPIO commit control registers provide a layer of protection against accidental programming of critical hardware signals including the GPIO pins that can function as JTAG/SWD signals and the **NMI** signal. The commit control process must be followed for these pins, even if they are programmed as alternate functions other than JTAG/SWD or **NMI**; see “Commit Control” on page 743.

**Note:** If the device fails initialization during reset, the hardware toggles the **TDO** output as an indication of failure. Thus, during board layout, designers should not designate the **TDO** pin as a GPIO in sensitive applications where the possibility of toggling could affect the design.

**Note:** The GPIO commit control registers provide a layer of protection against accidental programming of critical hardware peripherals. Protection is provided for the GPIO pins that can be used as the four JTAG/SWD pins and the **NMI** pin (see “Signal Tables” on page 1646 for pin numbers). Writes to protected bits of the **GPIO Alternate Function Select (GPIOAFSEL)** register (see page 762), **GPIO Pull Up Select (GPIOPUR)** register (see page 768), **GPIO Pull-Down Select (GPIOPDR)** register (see page 770), and **GPIO Digital Enable (GPIODEN)** register (see page 773) are not committed to storage unless the **GPIO Lock (GPIOLOCK)** register (see page 775) has been unlocked and the appropriate bits of the **GPIO Commit (GPIOCR)** register (see page 776) have been set.

| Value | Description  |
|-------|--|
| 0     | The corresponding pin's weak pull-down resistor is disabled. |
| 1     | The corresponding pin's weak pull-down resistor is enabled.  |

Setting a bit in the **GPIOPUR** register clears the corresponding bit in the **GPIOPDR** register. The change is effective on the next clock cycle.

### Register 17: GPIO Slew Rate Control Select (GPIOSLR), offset 0x518

The **GPIOSLR** register is the slew rate control register. Slew rate control is only available when using the 8-mA, 10-mA or 12-mA drive strength option. The selection of drive strength is done through the **GPIO Drive Select (GPIODRnR** registers and the **GPIO Peripheral Configuration (GPIOPC)** register.

**Note:** This register has no effect on port pins **PL6** and **PL7**.

#### GPIO Slew Rate Control Select (GPIOSLR)

|                   | 0        | Slew rate control is disabled for the corresponding pin. |           |   |  |
|                   | 1        | Slew rate control is enabled for the corresponding pin.  |           |   |  |

**Register 18: GPIO Digital Enable (GPIODEN), offset 0x51C**

**Note:** Pins configured as digital inputs are Schmitt-triggered.

The **GPIODEN** register is the digital enable register. By default, all GPIO signals except those listed below are configured out of reset to be undriven (tristate). Their digital function is disabled; they do not drive a logic value on the pin and they do not allow the pin voltage into the GPIO receiver. To use the pin as a digital input or output (either GPIO or alternate function), the corresponding **GPIODEN** bit must be set.

**Important:** The table below shows special consideration GPIO pins. Most GPIO pins are configured as GPIOs and tri-stated by default (**GPIOAFSEL**=0, **GPIODEN**=0, **GPIOPDR**=0, **GPIOPUR**=0, and **GPIOPCTL**=0). Special consideration pins may be programmed to a non-GPIO function or may have special commit controls out of reset. In addition, a Power-On-Reset ( $\overline{POR}$ ) returns these GPIO to their original special consideration state.

**Table 10-11. GPIO Pins With Special Considerations**

| GPIO Pins | Default Reset State | GPIOAFSEL | GPIODEN | GPIOPDR | GPIOPUR | GPIOPCTL | GPIOCR |
|-----------|---------------------|-----------|---------|---------|---------|----------|--------|
| PC[3:0]   | JTAG/SWD            | 1         | 1       | 0       | 1       | 0x1      | 0      |
| PD[7]     | GPIO <sup>a</sup>   | 0         | 0       | 0       | 0       | 0x0      | 0      |
| PE[7]     | GPIO <sup>a</sup>   | 0         | 0       | 0       | 0       | 0x0      | 0      |

a. This pin is configured as a GPIO by default but is locked and can only be reprogrammed by unlocking the pin in the **GPIOLOCK** register and uncommitting it by setting the **GPIOCR** register.

The GPIO commit control registers provide a layer of protection against accidental programming of critical hardware signals including the GPIO pins that can function as JTAG/SWD signals and the **NMI** signal. The commit control process must be followed for these pins, even if they are programmed as alternate functions other than JTAG/SWD or NMI; see “Commit Control” on page 743.

**Note:** If the device fails initialization during reset, the hardware toggles the **TDO** output as an indication of failure. Thus, during board layout, designers should not designate the **TDO** pin as a GPIO in sensitive applications where the possibility of toggling could affect the design.

**Note:** The GPIO commit control registers provide a layer of protection against accidental programming of critical hardware peripherals. Protection is provided for the GPIO pins that can be used as the four JTAG/SWD pins and the **NMI** pin (see “Signal Tables” on page 1646 for pin numbers). Writes to protected bits of the **GPIO Alternate Function Select (GPIOAFSEL)** register (see page 762), **GPIO Pull Up Select (GPIOPUR)** register (see page 768), **GPIO Pull-Down Select (GPIOPDR)** register (see page 770), and **GPIO Digital Enable (GPIODEN)** register (see page 773) are not committed to storage unless the **GPIO Lock (GPIOLOCK)** register (see page 775) has been unlocked and the appropriate bits of the **GPIO Commit (GPIOCR)** register (see page 776) have been set.

| Bit/Field | Name     | Type | Reset     | Description   |
|-----------|----------|------|-----------|---|
| 31:8      | reserved | RO   | 0x0000.00 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 7:0       | DEN      | RW   | -         | Digital Enable  |

| Value | Description   |
|-------|---|
| 0     | The digital functions for the corresponding pin are disabled. |
| 1     | The digital functions for the corresponding pin are enabled.  |

The reset value for this register is 0x0000.0000 for GPIO ports that are not listed in Table 10-1 on page 732.

## Register 19: GPIO Lock (GPIOLOCK), offset 0x520

The **GPIOLOCK** register enables write access to the **GPIOCR** register (see page 776). Writing 0x4C4F.434B to the **GPIOLOCK** register unlocks the **GPIOCR** register. Writing any other value to the **GPIOLOCK** register re-enables the locked state. Reading the **GPIOLOCK** register returns the lock status rather than the 32-bit value that was previously written. Therefore, when write accesses are disabled, or locked, reading the **GPIOLOCK** register returns 0x0000.0001. When write accesses are enabled, or unlocked, reading the **GPIOLOCK** register returns 0x0000.0000.

### GPIO Lock (GPIOLOCK)

GPIO Port A (AHB) base: 0x4005.8000  
 GPIO Port B (AHB) base: 0x4005.9000

 GPIO Port T (AHB) base: 0x4006.9000  
 Offset 0x520

Type RW, reset 0x0000.0001

| Bit/Field | Name | Type | Reset       | Description |
|-----------|------|------|-------------|-------------|
| 31:0      | LOCK | RW   | 0x0000.0001 | GPIO Lock   |

A write of the value 0x4C4F.434B unlocks the **GPIO Commit (GPIOCR)** register for write access. A write of any other value or a write to the **GPIOCR** register reapplies the lock, preventing any register updates. A read of this register returns the following values:

#### Value Description

- 0x1 The **GPIOCR** register is locked and may not be modified.
- 0x0 The **GPIOCR** register is unlocked and may be modified.

### Register 20: GPIO Commit (GPIOCR), offset 0x524

The **GPIOCR** register is the commit register. The value of the **GPIOCR** register determines which bits of the **GPIOAFSEL**, **GPIOPUR**, **GPIOPDR**, and **GPIODEN** registers are committed when a write to these registers is performed. If a bit in the **GPIOCR** register is cleared, the data being written to the corresponding bit in the **GPIOAFSEL**, **GPIOPUR**, **GPIOPDR**, or **GPIODEN** registers cannot be committed and retains its previous value. If a bit in the **GPIOCR** register is set, the data being written to the corresponding bit of the **GPIOAFSEL**, **GPIOPUR**, **GPIOPDR**, or **GPIODEN** registers is committed to the register and reflects the new value.

The contents of the **GPIOCR** register can only be modified if the status in the **GPIOLOCK** register is unlocked. Writes to the **GPIOCR** register are ignored if the status in the **GPIOLOCK** register is locked.

**Important:** This register is designed to prevent accidental programming of the registers that control connectivity to the NMI and JTAG/SWD debug hardware. By initializing the bits of the **GPIOCR** register to 0 for the NMI and JTAG/SWD pins (see “Signal Tables” on page 1646 for pin numbers), the NMI and JTAG/SWD debug port can only be converted to GPIOs through a deliberate set of writes to the **GPIOLOCK**, **GPIOCR**, and the corresponding registers.

Because this protection is currently only implemented on the NMI and JTAG/SWD pins (see “Signal Tables” on page 1646 for pin numbers), all of the other bits in the **GPIOCR** registers cannot be written with 0x0. These bits are hardwired to 0x1, ensuring that it is always possible to commit new values to the **GPIOAFSEL**, **GPIOPUR**, **GPIOPDR**, or **GPIODEN** register bits of these other pins.

| Bit/Field | Name     | Type | Reset        | Description   |
|-----------|----------|------|--------------|---|
| 31:8      | reserved | RO   | 0x0000.00    | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.   |
| 7:0       | CR       | -    | -            | GPIO Commit   |
|           |          |      |              | Value Description   |
|           |          |      | 0            | The corresponding <b>GPIOAFSEL</b> , <b>GPIOPUR</b> , <b>GPIOPDR</b> , or <b>GPIODEN</b> bits cannot be written.  |
|           |          |      | 1            | The corresponding <b>GPIOAFSEL</b> , <b>GPIOPUR</b> , <b>GPIOPDR</b> , or <b>GPIODEN</b> bits can be written.   |
|           |          |      | <b>Note:</b> | The default register type for the <b>GPIOCR</b> register is RO for all GPIO pins with the exception of the <b>NMI</b> pin and the four JTAG/SWD pins (see “Signal Tables” on page 1646 for pin numbers). These six pins are the only GPIOs that are protected by the <b>GPIOCR</b> register. Because of this, the register type for the corresponding GPIO Ports is RW.   |
|           |          |      |              | The default reset value for the <b>GPIOCR</b> register is 0x0000.00FF for all GPIO pins, with the exception of the <b>NMI</b> and JTAG/SWD pins (see “Signal Tables” on page 1646 for pin numbers). To ensure that the JTAG and <b>NMI</b> pins are not accidentally programmed as GPIO pins, these pins default to non-committable. Because of this, the default reset value of <b>GPIOCR</b> changes for the corresponding ports. |

## Register 21: GPIO Analog Mode Select (GPIOAMSEL), offset 0x528

**Important:** This register is only valid for ports and pins that can be used as ADC AINx inputs.

If any pin is to be used as an ADC input, the appropriate bit in **GPIOAMSEL** must be set to disable the analog isolation circuit.

The **GPIOAMSEL** register controls isolation circuits to the analog side of a unified I/O pad. Because the GPIOs may be driven by a 3.3-V source and affect analog operation, analog circuitry requires isolation from the pins when they are not used in their analog function.

Each bit of this register controls the isolation circuitry for the corresponding GPIO signal. For information on which GPIO pins can be used for ADC functions, refer to Table 28-5 on page 1693.

### GPIO Analog Mode Select (GPIOAMSEL)

GPIO Port A (AHB) base: 0x4005.8000  
 GPIO Port B (AHB) base: 0x4005.9000  
 GPIO Port C (AHB) base: 0x4005.A000  
 GPIO Port D (AHB) base: 0x4005.B000  
 GPIO Port E (AHB) base: 0x4005.C000  
 GPIO Port F (AHB) base: 0x4005.D000  
 GPIO Port G (AHB) base: 0x4005.E000  
 GPIO Port H (AHB) base: 0x4005.F000  
 GPIO Port J (AHB) base: 0x4006.0000  
 GPIO Port K (AHB) base: 0x4006.1000  
 GPIO Port L (AHB) base: 0x4006.2000  
 GPIO Port M (AHB) base: 0x4006.3000  
 GPIO Port N (AHB) base: 0x4006.4000  
 GPIO Port P (AHB) base: 0x4006.5000  
 GPIO Port Q (AHB) base: 0x4006.6000  
 GPIO Port R (AHB) base: 0x4006.7000  
 GPIO Port S (AHB) base: 0x4006.8000  
 GPIO Port T (AHB) base: 0x4006.9000  
 Offset 0x528

Type RW, reset 0x0000.0000

| Bit/Field | Name      | Type | Reset     | Description   |
|-----------|-----------|------|-----------|---|
| 31:8      | reserved  | RO   | 0x0000.00 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 7:0       | GPIOAMSEL | RW   | 0x00      | GPIO Analog Mode Select   |

| Value | Description   |
|-------|---|
| 0     | The analog function of the pin is disabled, the isolation is enabled, and the pin is capable of digital functions as specified by the other GPIO configuration registers. |
| 1     | The analog function of the pin is enabled, the isolation is disabled, and the pin is capable of analog functions.   |

**Note:** This register and bits are only valid for GPIO signals that share analog function through a unified I/O pad.

The reset state of this register is 0 for all signals.

## Register 22: GPIO Port Control (GPIOPCTL), offset 0x52C

The **GPIOPCTL** register is used in conjunction with the **GPIOAFSEL** register and selects the specific peripheral signal for each GPIO pin when using the alternate function mode. Most bits in the **GPIOAFSEL** register are cleared on reset, therefore most GPIO pins are configured as GPIOs by default. When a bit is set in the **GPIOAFSEL** register, the corresponding GPIO signal is controlled by an associated peripheral. The **GPIOPCTL** register selects one out of a set of peripheral functions for each GPIO, providing additional flexibility in signal definition. For information on the defined encodings for the bit fields in this register, refer to Table 28-5 on page 1693. The reset value for this register is 0x0000.0000 for GPIO ports that are not listed in the table below.

**Note:** If a particular input signal to a peripheral is assigned to two different GPIO port pins, the signal is assigned to the port with the lowest letter and the assignment to the higher letter port is ignored. If a particular output signal from a peripheral is assigned to two different GPIO port pins, the signal will output to both pins. Assigning an output signal from a peripheral to two different GPIO pins is not recommended.

**Important:** The table below shows special consideration GPIO pins. Most GPIO pins are configured as GPIOs and tri-stated by default (**GPIOAFSEL**=0, **GPIODEN**=0, **GPIOPDR**=0, **GPIOPUR**=0, and **GPIOPCTL**=0). Special consideration pins may be programmed to a non-GPIO function or may have special commit controls out of reset. In addition, a Power-On-Reset ( $\overline{POR}$ ) returns these GPIO to their original special consideration state.

**Table 10-12. GPIO Pins With Special Considerations**

| GPIO Pins | Default Reset State | GPIOAFSEL | GPIODEN | GPIOPDR | GPIOPUR | GPIOPCTL | GPIOCR |
|-----------|---------------------|-----------|---------|---------|---------|----------|--------|
| PC[3:0]   | JTAG/SWD            | 1         | 1       | 0       | 1       | 0x1      | 0      |
| PD[7]     | GPIO <sup>a</sup>   | 0         | 0       | 0       | 0       | 0x0      | 0      |
| PE[7]     | GPIO <sup>a</sup>   | 0         | 0       | 0       | 0       | 0x0      | 0      |

a. This pin is configured as a GPIO by default but is locked and can only be reprogrammed by unlocking the pin in the **GPIOLOCK** register and uncommitting it by setting the **GPIOCR** register.

The GPIO commit control registers provide a layer of protection against accidental programming of critical hardware signals including the GPIO pins that can function as JTAG/SWD signals and the **NMI** signal. The commit control process must be followed for these pins, even if they are programmed as alternate functions other than JTAG/SWD or **NMI**; see “Commit Control” on page 743.

**Note:** If the device fails initialization during reset, the hardware toggles the **TDO** output as an indication of failure. Thus, during board layout, designers should not designate the **TDO** pin as a GPIO in sensitive applications where the possibility of toggling could affect the design.

**Register 23: GPIO ADC Control (GPIOADCCTL), offset 0x530**

This register is used to configure a GPIO pin as a source for the ADC trigger.

Note that if the Port B **GPIOADCCTL** register is cleared, PB4 can still be used as an external trigger for the ADC. This is a legacy mode which allows code written for previous devices to operate on this microcontroller.

| 31:1      | reserved | RO   | 0x0000.000 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 0         | SUM      | RW   | 0          | Summary Interrupt   |

**Value Description**

0 All port pin interrupts are OR'ed together to produce a summary interrupt.

**Note:** The OR'ed summary interrupt occurs on bit 0 of the **GPIORIS** register. For summary interrupt mode, software should set the **GPIOIM** register to 0xFF and mask the port pin interrupts 1 through 7 in the **Interrupt Clear Enable (DISn)** register (see "NVIC Register Descriptions" on page 155). When servicing this interrupt, write a 1 to the corresponding bit in the **UNPENDn** register to clear the pending interrupt in the NVIC and clear the **GPIORIS** register pin interrupt bits by setting the **IC** field of the **GPIOICR** register to 0xFF.

1 Each pin has its own interrupt vector.

### Register 26: GPIO 12-mA Drive Select (GPIODR12R), offset 0x53C

The **GPIODR12R** register is the 12-mA drive control register. Each GPIO signal in the port can be individually configured without affecting the other pads.

**Note:** This register has no effect on port pins **PL6** and **PL7** or **PM[7:4]**.

#### GPIO 12-mA Drive Select (GPIODR12R)

GPIO Port A (AHB) base: 0x4005.8000  
 GPIO Port B (AHB) base: 0x4005.9000  
 GPIO Port C (AHB) base: 0x4005.A000  
 GPIO Port D (AHB) base: 0x4005.B000  
 GPIO Port E (AHB) base: 0x4005.C000

 GPIO Port S (AHB) base: 0x4006.8000  
 GPIO Port T (AHB) base: 0x4006.9000  
 Offset 0x53C  
 Type RW, reset 0x0000.0000

| Bit/Field | Name     | Type | Reset     | Description   |
|-----------|----------|------|-----------|---|
| 31:8      | reserved | RO   | 0x0000.00 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 7:0       | DRV12    | RW   | 0x00      | Output Pad 12-mA Drive Enable   |

| Value | Description   |
|-------|---|
| 0     | The drive for the corresponding GPIO pin is controlled by the <b>GPIODR2R</b> , <b>GPIODR4R</b> , and/or the <b>GPIODR8R</b> register.  |
| 1     | The corresponding GPIO pin has 12-mA drive. This encoding is only valid if the <b>GPIOPP</b> <b>EDE</b> bit is set and the appropriate <b>GPIOPC</b> <b>EDM</b> bit field is programmed to 0x3. |

**Note:** Please refer to Table 10-3 on page 744 for information on how to configure the drive strength.

Changes in the **GPIODR2R**, the **GPIODR4R** register and/or the **GPIODR8R** registers to configure 12 mA are effective on the next clock cycle.

**Register 27: GPIO Wake Pin Enable (GPIOWAKEPEN), offset 0x540**

This register is used to configure K[7:4] as a wake enable source for the hibernation module. The wake level must be programmed in the **GPIOWAKELVL** register at offset 0x544. In order for this register configuration to become implemented, the **WUUNLK** bit needs to be set in the **HIBIO** register at offset 0x02C in the hibernation module.

**Note:** This register is only available on Port K.

| 31:1              | reserved                               | RO   | 0x0   | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 0                 | EDE                                    | RO   | 0x1   | Extended Drive Enable<br>This bit specifies whether the extended drive capabilities are provided. Extended drive is configured by the EDM bits in the <b>GPIOPC</b> register.                 |
| Value Description |  |      |       |   |
| 0                 | No Extended Drive Capability provided. |      |       |   |
| 1                 | Extended Drive Capability provided.    |      |       |   |

**Register 31: GPIO Peripheral Configuration (GPIOPC), offset 0xFC4**

This **GPIOPC** register controls the extended drive modes of the GPIO and must be configured before the **GPIODRnR** registers in order for extended drive mode to take effect. When the **EDE** bit in **GPIOPP** register is set and the **EDMn** bit field is non-zero, the **GPIODRnR** registers do not drive their default value, but instead output an incremental drive strength, which has an additive effect. This allows for more drive strength possibilities. When the **EDE** bit is set and the **EDMn** bit field is non-zero, the 2 mA driver is always enabled. Any bits enabled in the **GPIODR4R** register will add an additional 2 mA; any bits set in the **GPIODR8R** add an extra 4 mA of drive. The **GPIODR12R** register is only valid when the **EDMn** value is 0x3. For this encoding, setting a bit in the **GPIODR12R** register adds 4 mA of drive to the already existing 8 mA, for a 12 mA drive strength. Table 10-3 on page 744 shows the drive capability options. If **EDMn** is 0x00, then the **GPIODR2R**, **GPIODR4R**, and **GPIODR8R** function as stated in their default register description.

**Table 10-13. GPIO Drive Strength Options**

| EDE (GPIOPP) | EDMn (GPIOPC) | GPIODR12R (+4mA) | GPIODR8R (+4mA) | GPIODR4R (+2mA) | GPIODR2R (2mA) | Drive (mA) |

## 11 External Peripheral Interface (EPI)

The External Peripheral Interface is a high-speed parallel bus for external peripherals or memory. It has several modes of operation to interface gluelessly to many types of external devices. The External Peripheral Interface is similar to a standard microprocessor address/data bus, except that it must typically be connected to just one type of external device. Enhanced capabilities include  $\mu$ DMA support, clocking control and support for external FIFO buffers.

The EPI has the following features:

- 8/16/32-bit dedicated parallel bus for external peripherals and memory
- Memory interface supports contiguous memory access independent of data bus width, thus enabling code execution directly from SDRAM, SRAM and Flash memory
- Blocking and non-blocking reads
- Separates processor from timing details through use of an internal write FIFO
- Efficient transfers using Micro Direct Memory Access Controller ( $\mu$ DMA)
  - Separate channels for read and write
  - Read channel request asserted by programmable levels on the internal Non-Blocking Read FIFO (NBRFIFO)
  - Write channel request asserted by empty on the internal Write FIFO (WFIFO)

The EPI supports three primary functional modes: Synchronous Dynamic Random Access Memory (SDRAM) mode, Traditional Host-Bus mode, and General-Purpose mode. The EPI module also provides custom GPIOs; however, unlike regular GPIOs, the EPI module uses a FIFO in the same way as a communication mechanism and is speed-controlled using clocking.

- Synchronous Dynamic Random Access Memory (SDRAM) mode
  - Supports x16 (single data rate) SDRAM at up to 60 MHz
  - Supports low-cost SDRAMs up to 64 MB (512 megabits)
  - Includes automatic refresh and access to all banks/rows
  - Includes a Sleep/Standby mode to keep contents active with minimal power draw
  - Multiplexed address/data interface for reduced pin count
- Host-Bus mode
  - Traditional x8 and x16 MCU bus interface capabilities
  - Similar device compatibility options as PIC, ATmega, 8051, and others
  - Access to SRAM, NOR Flash memory, and other devices, with up to 1 MB of addressing in non-multiplexed mode and 256 MB in multiplexed mode (512 MB in Host-Bus 16 mode with no byte selects)

- Support for up to 512 Mb PSRAM in quad chip select mode, with dedicated configuration register read and write enable.
- Support of both muxed and de-muxed address and data
- Access to a range of devices supporting the non-address FIFO x8 and x16 interface variant, with support for external FIFO (XFIFO) EMPTY and FULL signals
- Speed controlled, with read and write data wait-state counters
- Support for read/write burst mode to Host Bus
- Multiple chip select modes including single, dual, and quad chip selects, with and without ALE
- External iRDY signal provided for stall capability of reads and writes
- Manual chip-enable (or use extra address pins)
- General-Purpose mode
  - Wide parallel interfaces for fast communications with CPLDs and FPGAs
  - Data widths up to 32 bits
  - Data rates up to 150 MB/second
  - Optional "address" sizes from 4 bits to 20 bits
  - Optional clock output, read/write strobes, framing (with counter-based size), and clock-enable input
- General parallel GPIO
  - 1 to 32 bits, FIFOed with speed control
  - Useful for custom peripherals or for digital data acquisition and actuator controls

## **11.1 EPI Block Diagram**

Figure 11-1 on page 809 provides a block diagram of a TM4C129CNCZAD EPI module.

Figure 11-1. EPI Block Diagram

## 11.2 Signal Description

The following table lists the external signals of the EPI controller and describes the function of each. The EPI controller signals are alternate functions for GPIO signals and default to be GPIO signals at reset. The column in the table below titled "Pin Mux/Pin Assignment" lists the GPIO pin placement for the EPI signals. The `AFSEL` bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 762) should be set to choose the EPI controller function. The number in parentheses is the encoding that must be programmed into the `PMCn` field in the **GPIO Port Control (GPIOPTL)** register (page 779) to assign the EPI signals to the specified GPIO port pins. For more information on configuring GPIOs, see "General-Purpose Input/Outputs (GPIOs)" on page 731.

Table 11-1. External Peripheral Interface Signals (212BGA)

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type | Description            |

### 11.3 Functional Description

The EPI controller provides a glueless, programmable interface to a variety of common external peripherals such as SDRAM x 16, Host Bus x8 and x16 devices, RAM, NOR Flash memory, CPLDs and FPGAs. In addition, the EPI controller provides custom GPIO that can use a FIFO with speed control by using either the internal write FIFO (WFIFO) or the non-blocking read FIFO (NBRFIFO). The WFIFO can hold 4 words of data that are written to the external interface at the rate controlled by the **EPI Main Baud Rate (EPIBAUD)** registers. The NBRFIFO can hold 8 words of data and samples at the rate controlled by the **EPIBAUD** register. The EPI controller provides predictable operation and thus has an advantage over regular GPIO which has more variable timing due to on-chip bus arbitration and delays across bus bridges. Blocking reads stall the CPU until the transaction completes. Non-blocking reads are performed in the background and allow the processor

to continue operation. In addition, write data can also be stored in the WFIFO to allow multiple writes with no stalls.

**Note:** Both the `WTAV` bit field in the `EPIWFIFOCNT` register and the `WBUSY` bit in the `EPISTAT` register must be polled to determine if there is a current write transaction from the WFIFO. If both of these bits are clear, then a new bus access may begin.

Main read and write operations can be performed in subsets of the range `0x6000.0000` to `0xDFFF.FFFF`. A read from an address mapped location uses the offset and size to control the address and size of the external operation. When performing a multi-value load, the read is done as a burst (when available) to maximize performance. A write to an address mapped location uses the offset and size to control the address and size of the external operation. When performing a multi-value store, the write is done as a burst (when available) to maximize performance.

### 11.3.1 Master Access to EPI

The following lists the Bus Masters which have access to the EPI:

- CPU
- $\mu$ DMA

### 11.3.2 Non-Blocking Reads

The EPI Controller supports a special kind of read called a non-blocking read, also referred to as a posted read. Where a normal read stalls the processor or  $\mu$ DMA until the data is returned, a non-blocking read is performed in the background.

A non-blocking read is configured by writing the start address into a `EPIRADDRn` register, the size per transaction into a `EPIRSIZEn` register, and then the count of operations into a `EPIRPSTDn` register. After each read is completed, the result is written into the NBRFIFO and the `EPIRADDRn` register is incremented by the size (1, 2, or 4). The three most significant bits of `EPIRADDRn` register are only relevant in the Host Bus multi-chip select mode when they are used to enable the different chip selects.

If the NBRFIFO is filled, then the reads pause until space is made available. The NBRFIFO can be configured to interrupt the processor or trigger the  $\mu$ DMA based on fullness using the `EPIFIFOLVL` register. By using the trigger/interrupt method, the  $\mu$ DMA (or processor) can keep space available in the NBRFIFO and allow the reads to continue unimpeded.

When performing non-blocking reads, the SDRAM controller issues two additional read transactions after the burst request is terminated. The data for these additional transfers is discarded. This situation is transparent to the user other than the additional EPI bus activity and can safely be ignored.

Two non-blocking read register sets are available to allow sequencing and ping-pong use. When one completes, the other then activates. So, for example, if 20 words are to be read from `0x100` and 10 words from `0x200`, the `EPIRPSTD0` register can be set up with the read from `0x100` (with a count of 20), and the `EPIRPSTD1` register can be set up with the read from `0x200` (with a count of 10). When `EPIRPSTD0` finishes (count goes to 0), the `EPIRPSTD1` register then starts its operation. The NBRFIFO has then passed 30 values. When used with the  $\mu$ DMA, it may transfer 30 values (simple sequence), or the primary/alternate model may be used to handle the first 20 in one way and the second 10 in another. It is also possible to reload the `EPIRPSTD0` register when it is finished (and the `EPIRPSTD1` register is active); thereby, keeping the interface constantly busy.

To cancel a non-blocking read, the `EPIRPSTDn` register is cleared. Care must be taken, however if the register set was active to drain away any values read into the NBRFIFO and ensure that any read in progress is allowed to complete.

To ensure that the cancel is complete, the following algorithm is used (using the **EPIRPSTD0** register for example):

```
EPIRPSTD0 = 0;
while ((EPISTAT & 0x11) == 0x10)
; // we are active and busy
// if here, then other one is active or interface no longer busy
cnt = (EPIRADDR0 – original_address) / EPIRSIZE0; // count of values read
cnt -= values_read_so_far;
// cnt is now number left in FIFO
while (cnt-->0)
value = EPIREADFIFO; // drain
```

The above algorithm can be optimized in code; however, the important point is to wait for the cancel to complete because the external interface could have been in the process of reading a value when the cancel came in, and it must be allowed to complete.

### 11.3.3 DMA Operation

The  $\mu$ DMA can be used to achieve maximum transfer rates on the EPI through the NBRFIFO and the WFIFO. The  $\mu$ DMA has one channel for write and one for read. For writes, the **EPI DMA Transmit Count (EPIDMATXCNT)** register is programmed with the total number of transfers by the  $\mu$ DMA. An equivalent value is programmed into the **DMA Channel Control Word (DMACHCTL)** register of the  $\mu$ DMA at offset 0x008. A  $\mu$ DMA request is asserted by the EPI WRFIFO when the **TXCNT** value of the **EPIDMATXCNT** register is greater than zero and the **WTAV** bit field of the **EPIWFIFOCNT** register is less than the programmed threshold trigger, **WRFIFO**, of the **EPIFIFOLVL** register. The write channel continues to write data until the **TXCNT** value in the **EPIDMATXCNT** register is zero.

**Note:** When the **WRFIFO** bit in the **EPIFIFOLVL** register is set to 0x4 and the application bursts four words to an empty FIFO, the WRFIFO trigger may or may not deassert depending on if all four words were written to the WRFIFO or if the first word was passed immediately to the function requiring it. Thus, the application may not see the **WRRIS** bit in the **EPIRIS** register clear on a burst of four words.

The non-blocking read channel copies values from the NBRFIFO when the NBRFIFO is at the level specified by the **EPIFIFOLVL** register. For non-blocking reads, the start address, the size per transaction, and the count of elements must be programmed in the  $\mu$ DMA. Note that both non-blocking read register sets can be used, and they fill the NBRFIFO such that one runs to completion, then the next one starts (they do not interleave). Using the NBRFIFO provides the best possible transfer rate.

For blocking reads, the  $\mu$ DMA software channel (or another unused channel) is used for memory-to-memory transfers (or memory to peripheral, where some other peripheral is used). In this situation, the  $\mu$ DMA stalls until the read is complete and is not able to service another channel until the read is done. As a result, the arbitration size should normally be programmed to one access at a time. The  $\mu$ DMA controller can also transfer from and to the NBRFIFO and the WFIFO using the  $\mu$ DMA software channel in memory mode, however, the  $\mu$ DMA is stalled once the NBRFIFO is empty or the WFIFO is full. Note that when the  $\mu$ DMA controller is stalled, the core continues operation. See “Micro Direct Memory Access ( $\mu$ DMA)” on page 667 for more information on configuring the  $\mu$ DMA.

The size of the FIFOs must be taken into consideration when configuring the  $\mu$ DMA to transfer data to and from the EPI. The arbitration size should be 4 or less when writing to EPI address space and 8 or less when reading from EPI address space.

## 11.4 Initialization and Configuration

To enable and initialize the EPI controller, the following steps are necessary:

1. Enable the EPI module using the **RCGCEPI** register. See page 384.
2. Enable the clock to the appropriate GPIO module via the **RCGCGPIO** register. See page 380. To find out which GPIO port to enable, refer to “Signal Description” on page 809.
3. Set the GPIO **AFSEL** bits for the appropriate pins. See page 762. To determine which GPIOs to configure, see Table 28-4 on page 1680.
4. Configure the GPIO current level and/or slew rate as specified for the mode selected. See page 764 and page 772.
5. Configure the **PMC<sub>n</sub>** fields in the **GPIOPCTL** register to assign the EPI signals to the appropriate pins. See page 779 and Table 28-5 on page 1693.
6. Select the mode for the EPI block to SDRAM, HB8, HB16, or general parallel use, using the **MODE** field in the **EPI Configuration (EPICFG)** register. Set the mode-specific details (if needed) using the appropriate mode configuration **EPI Host Bus Configuration (EPIHBnCFGn)** registers for the desired chip-select configuration. Set the **EPI Main Baud Rate (EPIBAUD)** and **EPI Main Baud Rate 2 (EPIBAUD2)** register if the baud rate must be slower than the system clock rate.
7. Configure the address mapping using the **EPI Address Map (EPIADDRMAP)** register. The selected start address and range is dependent on the type of external device and maximum address (as appropriate). For example, for a 512-megabit SDRAM, program the **ERADR** field to 0x1 for address 0x6000.0000 or 0x2 for address 0x8000.0000; and program the **ERSZ** field to 0x3 for 256 MB. If using General-Purpose mode and no address at all, program the **EPADR** field to 0x1 for address 0xA000.0000 or 0x2 for address 0xC000.0000; and program the **EPSZ** field to 0x0 for 256 bytes.
8. To read or write directly, use the mapped address area (configured with the **EPIADDRMAP** register). Up to 4 or 5 writes can be performed at once without blocking. Each read is blocked until the value is retrieved.
9. To perform a non-blocking read, see “Non-Blocking Reads” on page 811.

**Note:** The application should not attempt to access externally until eight system clock cycles after the EPI has been fully configured.

**Note:** Once a **MODE** field has been programmed in the **EPICFG** register, the application should reset all configuration registers before re-programming to a new **MODE** value.

The following sub-sections describe the initialization and configuration for each of the modes of operation. Care must be taken to initialize everything properly to ensure correct operation. Control of the GPIO states is also important, as changes may cause the external device to interpret pin states as actions or commands (see “Register Descriptions” on page 749). Normally, a pull-up or pull-down is needed on the board to at least control the chip-select or chip-enable as the TM4C129CNCZAD GPIOs come out of reset in tri-state.

### 11.4.1 EPI Interface Options

There are a variety of memories and peripherals that can interface to the EPI module. Table 11-2 on page 814 shows the various configurations with their maximum performance.

**Table 11-2. EPI Interface Options**

| Interface                                    | Maximum Frequency |
|--|-------------------|
| Single SDRAM                                 | 60 MHz            |
| Single SRAM                                  | 60 MHz            |
| Single PSRAM without iRDY signal use         | 55 MHz            |
| Single PSRAM with iRDY signal use            | 52 MHz            |
| FPGAs, CPLDs, etc using General Purpose Mode | 60 MHz            |
| Memory configurations with 2 chip selects    | 40 MHz            |
| Memory configurations with 4 chip selects    | 20 MHz            |

### 11.4.2 SDRAM Mode

When activating the SDRAM mode, it is important to consider a few points:

1. Generally, it takes over 100  $\mu$ s from when the mode is activated to when the first operation is allowed. The SDRAM controller begins the SDRAM initialization sequence as soon as the mode is selected and enabled via the **EPICFG** register. It is important that the GPIOs are properly configured before the SDRAM mode is enabled, as the EPI controller is relying on the GPIO block's ability to drive the pins immediately. As part of the initialization sequence, the LOAD MODE REGISTER command is automatically sent to the SDRAM with a value of 0x27, which sets a CAS latency of 2 and a full page burst length.
2. The **INITSEQ** bit in the **EPI Status (EPISTAT)** register can be checked to determine when the initialization sequence is complete.
3. When using a frequency range and/or refresh value other than the default value, it is important to configure the **FREQ** and **RFSH** fields in the **EPI SDRAM Configuration (EPISDRAMCFG)** register shortly after activating the mode. After the 100- $\mu$ s startup time, the EPI block must be configured properly to keep the SDRAM contents stable.
4. The **SLEEP** bit in the **EPISDRAMCFG** register may be configured to put the SDRAM into a low-power self-refreshing state. It is important to note that the SDRAM mode must not be disabled once enabled, or else the SDRAM is no longer clocked and the contents are lost.
5. Before entering SLEEP mode, make sure all non-blocking reads and normal reads and writes have completed. If the system is running at 30 to 50 MHz, wait 2 EPI clocks after clearing the **SLEEP** bit before executing non-blocking reads, or normal reads and writes. If the system is configured to greater than 50 MHz, wait 5 EPI clocks before read and write transactions. For all other configurations, wait 1 EPI clock.

The **SIZE** field of the **EPISDRAMCFG** register must be configured correctly based on the amount of SDRAM in the system.

The **FREQ** field must be configured according to the value that represents the range being used. Based on the range selected, the number of external clocks used between certain operations (for example, PRECHARGE or ACTIVATE) is determined. If a higher frequency is given than is used, then the only downside is that the peripheral is slower (uses more cycles for these delays). If a lower frequency is given, incorrect operation occurs.

See “External Peripheral Interface (EPI)” on page 1740 for timing details for the SDRAM mode.

### 11.4.2.1 External Signal Connections

Table 11-3 on page 815 defines how EPI module signals should be connected to SDRAMs. The table applies when using a x16 SDRAM up to 512 megabits. Note that the EPI signals must use 8-mA drive when interfacing to SDRAM, see page 766. Any unused EPI controller signals can be used as GPIOs or another alternate function.

**Table 11-3. EPI SDRAM x16 Signal Connections**

| EPI Signal      | SDRAM Signal <sup>a</sup> |     |
|-----------------|---------------------------|-----|
| EPI0S0          | A0                        | D0  |
| EPI0S1          | A1                        | D1  |
| EPI0S2          | A2                        | D2  |
| EPI0S3          | A3                        | D3  |
| EPI0S4          | A4                        | D4  |
| EPI0S5          | A5                        | D5  |
| EPI0S6          | A6                        | D6  |
| EPI0S7          | A7                        | D7  |
| EPI0S8          | A8                        | D8  |
| EPI0S9          | A9                        | D9  |
| EPI0S10         | A10                       | D10 |
| EPI0S11         | A11                       | D11 |
| EPI0S12         | A12 <sup>b</sup>          | D12 |
| EPI0S13         | BA0                       | D13 |
| EPI0S14         | BA1                       | D14 |
| EPI0S15         | D15                       |     |
| EPI0S16         | DQML                      |     |
| EPI0S17         | DQMH                      |     |
| EPI0S18         | CASn                      |     |
| EPI0S19         | RASn                      |     |
| EPI0S20-EPI0S27 | not used                  |     |
| EPI0S28         | WEn                       |     |
| EPI0S29         | CSn                       |     |
| EPI0S30         | CKE                       |     |
| EPI0S31         | CLK                       |     |

a. If two signals are listed, connect the EPI signal to both pins.

b. Only for 256/512 megabit SDRAMs.

### 11.4.2.2 Refresh Configuration

The refresh count is based on the external clock speed and the number of rows per bank as well as the refresh period. The *RFSH* field represents how many external clock cycles remain before an AUTO-REFRESH is required. The normal formula is:

$$RFSH = (t_{Refresh\_us} / number\_rows) / ext\_clock\_period$$

A refresh period is normally 64 ms, or 64000  $\mu$ s. The number of rows is normally 4096 or 8192. The *ext\_clock\_period* is a value expressed in  $\mu$ sec and is derived by dividing 1000 by the clock speed

expressed in MHz. So, 50 MHz is  $1000/50=20$  ns, or  $0.02 \mu\text{s}$ . A typical SDRAM is 4096 rows per bank if the system clock is running at 50 MHz with an **EPIBAUD** register value of 0:

$$RFSH = (64000/4096) / 0.02 = 15.625 \mu\text{s} / 0.02 \mu\text{s} = 781.25$$

The default value in the `RFSH` field is 750 decimal or `0x2EE` to allow for a margin of safety and providing  $15 \mu\text{s}$  per refresh. It is important to note that this number should always be smaller or equal to what is required by the above equation. For example, if running the external clock at 25 MHz (40 ns per clock period), 390 is the highest number that may be used. Note that the external clock may be 25 MHz when the system clock is 25 MHz or when the system clock is 50 MHz and configuring the `COUNT0` field in the **EPIBAUD** register to 1 (divide by 2).

If a number larger than allowed is used, the SDRAM is not refreshed often enough, and data is lost.

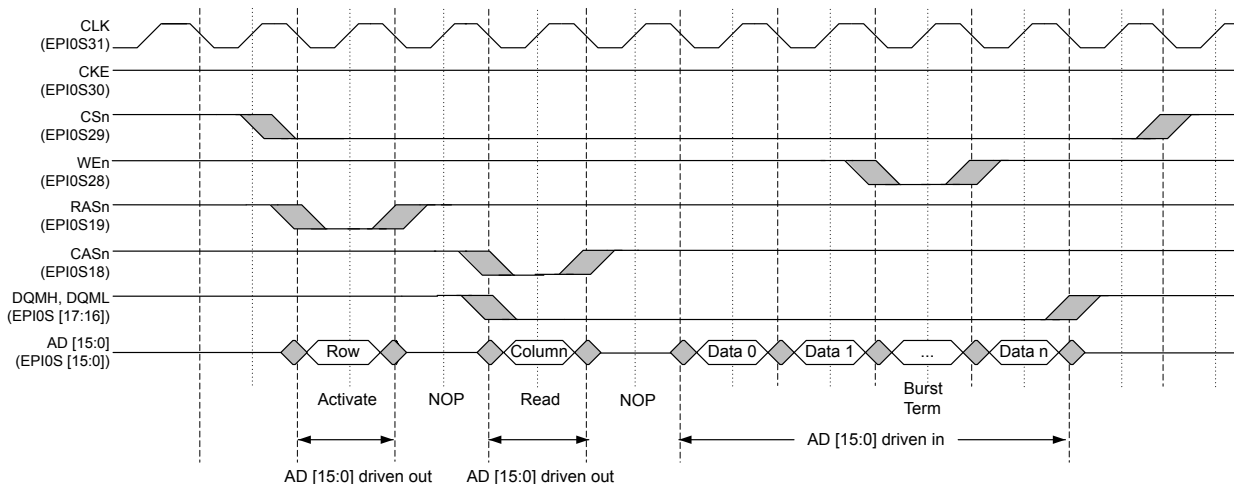

### 11.4.2.3 Bus Interface Speed

The EPI Controller SDRAM interface can operate up to 60 MHz. The `COUNT0` field in the **EPIBAUD** register configures the speed of the EPI clock. For system clock (`SysClk`) speeds up to 60 MHz, the `COUNT0` field can be `0x0000`, and the SDRAM interface can run at the same speed as `SysClk`. However, if `SysClk` is running at higher speeds, the bus interface can run only as fast as half speed, and the `COUNT0` field must be configured to at least `0x0001`.

### 11.4.2.4 Non-Blocking Read Cycle

Figure 11-2 on page 816 shows a non-blocking read cycle of  $n$  halfwords;  $n$  can be any number greater than or equal to 1. The cycle begins with the Activate command and the row address on the `EPIOS[15:0]` signals. With the programmed CAS latency of 2, the Read command with the column address on the `EPIOS[15:0]` signals follows after 2 clock cycles. Following one more NOP cycle, data is read in on the `EPIOS[15:0]` signals on every rising clock edge. The Burst Terminate command is issued during the cycle when the next-to-last halfword is read in. The `DQMH` and `DQML` signals are deasserted after the last halfword of data is received; the `CSn` signal deasserts on the following clock cycle, signaling the end of the read cycle. At least one clock period of inactivity separates any two SDRAM cycles.

Figure 11-2. SDRAM Non-Blocking Read Cycle

### 11.4.2.5 Normal Read Cycle

Figure 11-3 on page 817 shows a normal read cycle of  $n$  halfwords;  $n$  can be 1 or 2. The cycle begins with the Activate command and the row address on the  $EPIOS[15:0]$  signals. With the programmed CAS latency of 2, the Read command with the column address on the  $EPIOS[15:0]$  signals follows after 2 clock cycles. Following one more NOP cycle, data is read in on the  $EPIOS[15:0]$  signals on every rising clock edge. The DQMH, DQML, and CSn signals are deasserted after the last halfword of data is received, signaling the end of the cycle. At least one clock period of inactivity separates any two SDRAM cycles.

Figure 11-3. SDRAM Normal Read Cycle

### 11.4.2.6 Write Cycle

Figure 11-4 on page 818 shows a write cycle of  $n$  halfwords;  $n$  can be any number greater than or equal to 1. The cycle begins with the Activate command and the row address on the  $EPIOS[15:0]$  signals. With the programmed CAS latency of 2, the Write command with the column address on the  $EPIOS[15:0]$  signals follows after 2 clock cycles. When writing to SDRAMs, the Write command is presented with the first halfword of data. Because the address lines and the data lines are multiplexed, the column address is modified to be (programmed address - 1). During the Write command, the DQMH and DQML signals are high, so no data is written to the SDRAM. On the next clock, the DQMH and DQML signals are asserted, and the data associated with the programmed address is written. The Burst Terminate command occurs during the clock cycle following the write of the last halfword of data. The WEn, DQMH, DQML, and CSn signals are deasserted after the last halfword of data is received, signaling the end of the access. At least one clock period of inactivity separates any two SDRAM cycles.

Figure 11-4. SDRAM Write Cycle

### 11.4.3 Host Bus Mode

Host Bus supports the traditional 8-bit and 16-bit interfaces popularized by the 8051 devices and SRAM devices, as well as PSRAM and NOR Flash memory. This interface is asynchronous and uses strobe pins to control activity. Addressable memory can be doubled using Host Bus-16 mode as it performs half-word accesses. The `EPIOS0` is the LSB of the address and is equivalent to the internal Cortex-M4 A1 address. `EPIOS0` should be connected to A0 of 16-bit memories.

#### 11.4.3.1 Control Pins

The main three strobes are Address Latch Enable (ALE), Write (`WRn`), and Read (`RDn`, sometimes called `OEn`). Note that the timings are designed for older logic and so are hold-time versus setup-time specific. The polarity of the read and write strobes can be active High or active Low by clearing or setting the `RDHIGH` and `WRHIGH` bits in the **EPI Host-Bus n Configuration (EPIHBnCFGn)** register.

The ALE can be changed to an active-low chip select signal, `CSn`, through the **EPIHBnCFGn** register. The ALE is best used for Host-Bus muxed mode in which EPI address and data pins are shared. All Host-Bus accesses have an address phase followed by a data phase. The ALE indicates to an external latch to capture the address then hold it until the data phase. The polarity of the ALE can be active High or Low by clearing or setting the `ALEHIGH` bit in the **EPI Host-Bus n Configuration (EPIHBnCFGn)** register. `CSn` is best used for Host-Bus unmuxed mode in which EPI address and data pins are separate. The `CSn` indicates when the address and data phases of a read or write access are occurring. Both the ALE and the `CSn` modes can be enhanced to access four external devices using settings in the **EPIHBnCFGn** register. PSRAM accesses must use both ALE and `CSn`. Wait states can be added to the data phase of the access using the `WRWS` and `RDWS` bits in the **EPIHBnCFGn** register. Additionally, within these wait state options, the `WRWSM` and `RDWSM` bit of the **EPIHBnTIMEn** register can be set to reduce the given wait states by 1 EPI clock cycle for finer granularity.

For FIFO mode, the ALE is not used, and two input holds are optionally supported to gate input and output to what the XFIFO can handle. FIFO mode is only applicable in EPI asynchronous mode.

Host-Bus 8 and Host-Bus 16 modes are very configurable. The user has the ability to connect 1, 2, or 4 external devices to the EPI signals, as well as control whether byte select signals are provided in HB16 mode. These capabilities depend on the configuration of the `MODE` field in the **EPIHBnCFG**

register, the **CSCFG** field and the **CSCFGEXT** bit in the **EPIHBnCFGn** register, and the **BSEL** bit in the **EPIHB16CFG** register. The **CSCFGEXT** bit extends the chip select configuration possibilities by providing the most significant bit of the **CSCFG** field. Refer to Table 11-4 on page 819 for the possible ALE and chip select options that can be programmed by the combination of the **CSCFGEXT** and **CSCFG** bits. Note that **CSCFGEXT** is the most significant bit.

**Table 11-4. CSCFGEXT + CSCFG Encodings**

| Value | Description   |
|-------|---|
| 0x0   | ALE Configuration<br>EPIOS30 is used as an address latch (ALE). The ALE signal is generally used when the address and data are muxed (MODE field in the EPIHB8CFG register is 0x0). The ALE signal is used by an external latch to hold the address through the bus cycle.  |
| 0x1   | CSn Configuration<br>EPIOS30 is used as a Chip Select (CSn). When using this mode, the address and data are generally not muxed (MODE field in the EPIHB8CFG register is 0x1). However, if address and data muxing is needed, the WR signal (EPIOS29) and the RD signal (EPIOS28) can be used to latch the address when CSn is low.                   |
| 0x2   | Dual CSn Configuration<br>EPIOS30 is used as CS0n and EPIOS27 is used as CS1n. Whether CS0n or CS1n is asserted is determined by the most significant address bit for a respective external address map. This configuration can be used for a RAM bank split between 2 devices as well as when using both an external RAM and an external peripheral. |
| 0x3   | ALE with Dual CSn Configuration<br>EPIOS30 is used as address latch (ALE), EPIOS27 is used as CS1n, and EPIOS26 is used as CS0n. Whether CS0n or CS1n is asserted is determined by the most significant address bit for a respective external address map.  |
| 0x4   | ALE with Single CSn Configuration<br>EPIOS30 is used as address latch (ALE) and EPIOS27 is used as CSn.   |
| 0x5   | Quad CSn Configuration<br>EPIOS30 is used as CS0n and EPIOS27 is used as CS1n. EPIOS34 is used as CS2n and EPIOS33 is used as CS3n.   |
| 0x6   | ALE with Quad CSn Configuration<br>EPIOS30 is ALE, EPIOS26 is CS0n and EPIOS27 is used as CS1n. EPIOS34 is used as CS2n and EPIOS33 is used as CS3n.  |
| 0x7   | Reserved  |

If one of the Dual-Chip-Select modes is selected (**CSCFGEXT** is 0x0 and **CSCFG** is 0x2 or 0x3 in the **EPIHBnCFGn** register), both chip selects can share the peripheral, code, or the memory space, or one chip select can use the peripheral space and the other can use the memory or code space. In the **EPIADDRMAP** register, if the **EPADR** field is not 0x0, the **ECADR** field is 0x0, and the **ERADR** field is 0x0, then the address specified by **EPADR** is used for both chip selects, with **CS0n** being asserted when the MSB of the address range is 0 and **CS1n** being asserted when the MSB of the address range is 1. If the **ERADR** field is not 0x0, the **ECADR** field is 0x0, and the **EPADR** field is 0x0, then the address specified by **ERADR** is used for both chip selects, with the MSB performing the same delineation. If both the **EPADR** and the **ERADR** are not 0x0, and the **ECADR** field is 0x0 and the EPI is configured for dual-chip selects, then **CS0n** is asserted for either address range defined by **EPADR** and **CS1n** is asserted for either address range defined by **ERADR**. The two chip selects can also be shared between the code space and memory or peripheral space. If the **ECADR** field is 0x1, **ERADR** field is 0x0, and the **EPADR** field is not 0x0, then **CS0n** is asserted for the address range defined by **ECADR** and **CS1n** is asserted for either address range defined by **EPADR**. If the **ECADR** field is 0x1, **EPADR** field is 0x0, and the **ERADR** field is not 0x0, then **CS0n** is asserted for the address range defined by **ECADR** and **CS1n** is asserted for either address range defined by **ERADR**.

In quad chip select mode (*CSCFGEXT* is 0x1 and *CSCFG* is 0x1 or 0x2 in the **EPIHBnCFG2** register), both the peripheral and the memory space must be enabled. In the **EPIADDRMAP** register, the *EPADR* field is 0x3, the *ERADR* field is 0x3, and the *ECADR* field is 0x0. With this configuration, *CS0n* asserts for the address range beginning at 0x6000.0000, *CS1n* asserts for 0x8000.0000, *CS2n* for 0xA000.0000, and *CS3n* for 0xC000.0000. Table 11-5 on page 820 gives a detailed explanation of chip select address range mappings based on combinations of enabled peripheral and memory space.

**Note:** Only one memory area can be mapped to a single chip select. Enabling multiple memory areas for one chip select may produce unexpected results.

**Table 11-5. Dual- and Quad- Chip Select Address Mappings**

| Chip Select Mode | ERADR      | EPADR      | ECADR | CS0 <sup>a</sup>  | CS1  | CS2         | CS3         |
|------------------|------------|------------|-------|---|--|-------------|-------------|
| Dual-chip select | 0x0        | 0x1 or 0x2 | 0x0   | EPADR defined address range (0xA000.000 or 0xC000.0000) | EPADR defined address range (0xA000.000 or 0xC000.0000)  | N/A         | N/A         |
| Dual-chip select | 0x1 or 0x2 | 0x0        | 0x0   | ERADR defined address range (0x6000.000 or 0x8000.000)  | ERADR defined address range (0x6000.000 or 0x8000.000)   | N/A         | N/A         |
| Dual-chip select | 0x1 or 0x2 | 0x1 or 0x2 | 0x0   | EPADR defined address range (0xA000.000 or 0xC000.0000) | ERADR defined address range (0x6000.000 or 0x8000.000)   | N/A         | N/A         |
| Dual-chip select | 0x0        | 0x1 or 0x2 | 0x1   | ECADR defined address range (0x1000.000)                | EPADR defined address range (0xA000.0000 or 0xC000.0000) | N/A         | N/A         |
| Dual-chip select | 0x1 or 0x2 | 0x0        | 0x1   | ECADR defined address range (0x1000.000)                | ERADR defined address range (0x6000.000 or 0x8000.000)   | N/A         | N/A         |
| Quad-chip select | 0x3        | 0x3        | 0x0   | 0x6000.0000   | 0x8000.0000  | 0xA000.0000 | 0xC000.0000 |

a. When *CS0* & *CS1* share address space, *CS0* asserts when the MSB of the address is 0 and *CS1*, when the MSB of the address is '1.'

The *MODE* field of the **EPIHBnCFGn** registers configure the interface for the chip selects, which support *ADMUX* or *ADNOMUX*. See Table 11-6 on page 821 for details on which configuration register controls each chip select. If the *CSBAUD* bit is clear, all chip selects are configured by the *MODE* bit field of the **EPIHBnCFG** register.

If the *CSBAUD* bit in the **EPIHBnCFG2** register is set in Dual-chip select mode, the 2 chip selects can use different clock frequencies, wait states and strobe polarity. If the *CSBAUD* bit is clear, both chip selects use the clock frequency, wait states, and strobe polarity defined for *CS0n*. Additionally, if the *CSBAUD* bit is set, the two chip selects can use different interface modes. If any interface modes are programmed to *ADMUX*, then dual chip select mode must include the *ALE* capability. In quad chip select mode, if the *CSBAUD* bit in the **EPIHBnCFG2** register is set, the 4 chip selects can use different clock frequencies, wait states and strobe polarity. If the *CSBAUD* bit is clear, all chip selects use the clock frequency, wait states, and strobe polarity defined for *CS0n*. If the *CSBAUD* bit is set, the four chip selects can use different interface modes.

**Table 11-6. Chip Select Configuration Register Assignment**

| Configuration Register <sup>a</sup> | Corresponding Chip Select |
|-------------------------------------|---------------------------|
| EPIHBnCFG                           | CS0n                      |
| EPIHBnCFG2                          | CS1n                      |
| EPIHBnCFG3                          | CS2n                      |
| EPIHBnCFG4                          | CS3n                      |

a. If the CSBAUD bit in the **EPIHBnCFG2** register is clear and multiple chip selects are enabled, then all chip selects are configured by the MODE bit field in the **EPIHBnCFG** register.

Note that multiple chip select modes do not allow the intermixing of Host-Bus 8 and Host-Bus16 modes.

When BSEL=1 in the **EPIHB16CFG** register, byte select signals are provided, so byte-sized data can be read and written at any address, however these signals reduce the available address width by 2 pins. The byte select signals are active Low. BSEL0n corresponds to the LSB of the halfword, and BSEL1n corresponds to the MSB of the halfword.

When BSEL=0, byte reads and writes at odd addresses only act on the even byte, and byte writes at even addresses write invalid values into the odd byte. As a result, accesses should be made as half-words (16-bits) or words (32-bits). In C/C++, programmers should use only short int and long int for accesses. Also, because data accesses in HB16 mode with no byte selects are on 2-byte boundaries, the available address space is doubled. For example, 28 bits of address accesses 512 MB in this mode. Table 11-7 on page 821 shows the capabilities of the HB8 and HB16 modes as well as the available address bits with the possible combinations of these bits.

Although the EPI0S31 signal can be configured for the EPI clock signal in Host-Bus mode, it is not required and should be configured as a GPIO to reduce EMI in the system.

**Table 11-7. Capabilities of Host Bus 8 and Host Bus 16 Modes**

| Host Bus Type | MODE | CSCFGEXT | CSCFG    | Max # of External Devices | BSEL | Byte Access | Available Address | Addressable Memory |
|---------------|------|----------|----------|---------------------------|------|-------------|-------------------|--------------------|
| HB8           | 0x0  | 0        | 0x0, 0x1 | 1                         | N/A  | Always      | 28 bits           | 256 MB             |
| HB8           | 0x0  | 0        | 0x2      | 2                         | N/A  | Always      | 27 bits           | 128 MB             |

a. If byte selects are not used, data accesses are on 2-byte boundaries. As a result, the available address space is doubled.

b. Two EPI signals are used for byte selects, reducing the available address space by two bits.

Table 11-8 on page 823 shows how the EPI[31:0] signals function while in Host-Bus 8 mode. Notice that the signal configuration changes based on the address/data mode selected by the MODE

field in the **EPIHB8CFGn** register and on the chip select configuration selected by the **CSCFG** and **CSCFGEXT** field in the **EPIHB8CFG2** register.

Although the **EPI0S31** signal can be configured for the EPI clock signal in Host-Bus mode, it is not required and should be configured as a GPIO to reduce EMI in the system. Any unused EPI controller signals can be used as GPIOs or another alternate function.

**Table 11-8. EPI Host-Bus 8 Signal Connections**

| EPI Signal | CSCFG          | HB8 Signal (MODE =ADMUX) | HB8 Signal (MODE =ADNOMUX (Cont. Read)) | HB8 Signal (MODE =XFIFO) |
|------------|----------------|--------------------------|---|--------------------------|
| EPI0S0     | X <sup>a</sup> | AD0                      | D0                                      | D0                       |
| EPI0S1     | X              | AD1                      | D1                                      | D1                       |
| EPI0S2     | X              | AD2                      | D2                                      | D2                       |

a. "X" indicates the state of this field is a don't care.

b. When an entry straddles several row, the signal configuration is the same for all rows.

c. The clock signal is not required for this mode.

Table 11-9 on page 825 shows how the EPI[31:0] signals function while in Host-Bus 16 mode. Notice that the signal configuration changes based on the address/data mode selected by the MODE field in the **EPIHB16CFGn** register, on the chip select configuration selected by the CSCFG and CSCFGEXT field in the same register, and on whether byte selects are used as configured by the BSEL bit in the **EPIHB16CFG** register.

Although the EPI0S31 signal can be configured for the EPI clock signal in Host-Bus mode, it is not required and should be configured as a GPIO to reduce EMI in the system. Any unused EPI controller signals can be used as GPIOs or another alternate function.

Table 11-9. EPI Host-Bus 16 Signal Connections

| EPI Signal | CSCFG          | BSEL | HB16 Signal (MODE =ADMUX) | HB16 Signal (MODE =ADNOMUX (Cont. Read)) | HB16 Signal (MODE =XFIFO) |

a. "X" indicates the state of this field is a don't care.

b. In this mode, half-word accesses are used. A0 is the LSB of the address and is equivalent to the internal Cortex-M3 A1 address. This pin should be connected to A0 of 16-bit memories.

c. When an entry straddles several row, the signal configuration is the same for all rows.

d. The clock signal is not required for this mode.

The `RDYEN` in the `EPIHBnCFG` enables the monitoring of the external `iRDY` pin to stall accesses. On the rising edge of EPI clock, if `iRDY` is low, access is stalled. The `IRDYDLY` can program the number of EPI clock cycles in advance to the stall (1,2 or 3) as shown in Figure 11-5 on page 828. This is a conceptual timing diagram of how the `iRDY` signal works with different `IRDYDLY` configurations. When enabled, the `iRDY` stalls the EPI's internal states, while `IRDYDLY` controls the delay pipeline when this stall takes affect. The `iRDY` signal can be connected to multiple devices with a pull up resistor as shown in Figure 11-6 on page 828. Note that when multiple PSRAMs are connected to `iRDY`, the `EPIHPnCFG` registers must be programmed to the same `iRDY` signal polarity through the `IRDYINV` bit. When connected to a PSRAM, `iRDY` is used to control the address to data latency.

Figure 11-6. `iRDY` Signal Connection

### 11.4.3.2 PSRAM Support

The EPI Host Bus supports both a synchronous and asynchronous interface to PSRAM memory when configured in 16-bit bus multiplexed mode. The `EPIHBPSRAM` register holds the values for the PSRAM's bus configuration registers (CR). The contents of the `EPIHBPSRAM` register can be sent to different memories depending on which `WRCRE` or `RDCRE` bit is set in the various `EPIHB16CFGn` registers. For example, if the `WRCRE` bit is enabled in `EPIHB16CFG`, then the `CRE` signal asserts and the contents are sent to the memory enabled by `CS0`. Enabling the `WRCRE` or `RDCRE` bit in `EPIHB16CFG2` register activates `CS1n` during a PSRAM configuration register write or read. The `WRCRE` and `RDCRE` bit in `EPIHB16CFG3` corresponds to `CS2n` and `EPIHB16CFG4`, to `CS3n`. The `WRCRE` bit clears when the transfer is done. There must not be any system access or

non-blocking read activity during the CRE read or write-enable transfer. During a write to the PSRAM's CR, the configuration data is written out on data pins [20:0] of the EPI bus. For a PSRAM configuration read access, the `RDCRE` bit in the **EPIHB16CFG** register is set to signal that the next access is a read of the PSRAM configuration register (CR). The address for the CR is written to bits `CR[19:18]` of the **EPIHBPSRAM** register. The read data is returned at `CR` bits [15:0] of the **EPIHBPSRAM** register.

- Note:**
- CRE read and write operations may only occur in asynchronous mode. During synchronous mode the CRE bit should be disabled. Setting the CRE bit during synchronous PSRAM accesses can lead to unpredictable behavior.
  - When the chip select is programmed to access the PSRAM, the `MODE` bit of the **EPIHBnCFGn** register must be programmed to enable address and data muxed (ADMUX). Page mode accesses are not supported by the EPI.
  - BURST is optimized for word-length bursting for SDRAM and PSRAM accesses.

The subsequent list identifies the steps for initializing the PSRAM interface:

1. Follow the EPI initialization steps in "Initialization and Configuration" on page 813.
2. Enable Host Bus 16 Mode by setting the `MODE` bits in the **EPICFG** register to 0x13. Choose between an integer or formula clock divide for the baud rate by configuring the `INTDIV` bit in the **EPICFG** register.
3. Configure the **EPIBAUD** register to the desired baud rate.
4. Since the EPI module only supports asynchronous programming of the configuration registers, clock gate the EPI clock by programming both the `CLKGATE` and `CLKGATEI` bits in the **EPIHB16CFG** register to 0.
5. Prepare for writing the PSRAM's Bus Configuration Register by setting the `ALEHIGH = 1` and `MODE=0x0` in the **EPIHB16CFG** register.
6. Program the **EPIHBPSRAM** register to be loaded into the CR register of the PSRAM by configuring bits [21:0].
  - `CR[20:19] = 0x0`, reserved
  - `CR[19:18] = 0x2` to enable configuring of the CR register
  - `CR[15] = 0x1` to enable asynchronous access
  - `CR[14] = 0` if the `iRDY` signal is used for memory transfers; if the design will not use the `iRDY` signal `CR[14]` should be cleared.
  - `CR[13:11]` must be programmed to have a matching read and write wait state configuration as is programmed in the **EPIHB16CFG** and **EPIHB16TIME** register.
  - `CR[10]` configures the polarity of the `WAIT` signal and should match the configuration of the `IRDYINV` bit in the **EPIHB16CFG** register.
  - `CR[8] = 0x1` to configure the appropriate wait configuration of the data
  - `CR[2:0] = 0x7` since the EPI interface in PSRAM mode is a continuous burst access.

7. Set the `WRCRE` bit in the **EPIHB16CFGn** register to initiate a write from the **EPIHBPSRAM** register to PSRAM's CR register.

**Note:** If the PSRAM's CR register must be reprogrammed after initialization, the application should allow the previous transfer to complete before beginning configuration to ensure proper PSRAM functionality.

**Table 11-10. PSRAM Fixed Latency Wait State Configuration**

| Latency Counter | Latency in Clocks | RDWS[1:0]/WRWS[1:0] | RWSM/WRWSM |
|-----------------|-------------------|---------------------|------------|
| BCR Code 2      | 3                 | 0x0                 | 0          |
| BCR Code 3      | 4                 | 0x1                 | 1          |
| BCR Code 4      | 5                 | 0x1                 | 0          |
| BCR Code 5      | 6                 | 0x2                 | 1          |
| BCR Code 6      | 7                 | 0x2                 | 0          |
| BCR Code 8      | 9                 | 0x3                 | 0          |

In variable initial latency mode, the memory's WAIT (iRDY) pin guides the EPI module when to read and write. The WAIT (iRDY) pin stalls the access for the duration of the latency and adds cycles if there is a refresh collision. To get the best performance, set `CR[13:11] = 0x2`, the `WRWS` field of the **EPIHB16CFG** register to 0x0, and the `WRWSM` and `RDWSM` bit of the **EPI16TIMEn** register to 0. For the WAIT pin to be recognized correctly set the `IRDYDLY` bit in the **EPI16TIMEn** register to 1 and the `CR[8] = 1` in the **EPIHBPSRAM** register.

**Note:** Wait state latency works differently in PSRAM Burst mode than in other modes. In PSRAM Burst mode the `RDWS` and `WRWS` bit fields define the latency for only the first access of the write or read cycle. Every access after that is a single access.

Figure 11-7 on page 831 and Figure 11-8 on page 831 depict a PSRAM burst read and write.

Figure 11-7. PSRAM Burst Read

Figure 11-8. PSRAM Burst Write

Note that if a read or write transfer attempts to begin during a refresh event, the transfer is held off by the assertion of the iRDY pin by the memory to the EPI module. Figure 11-9 on page 832 and Figure 11-10 on page 833 depict the delay in data transfer during a refresh collision.

**Figure 11-9. Read Delay During Refresh Event**

**Figure 11-10. Write Delay During Refresh Event**

### 11.4.3.3 Host Bus 16-bit Muxed Interface

Figure 11-11 on page 834 shows how to connect the EPI signals to a 16-bit SRAM and a 16-bit Flash memory with muxed address and memory using byte selects and dual chip selects with ALE. This schematic is just an example of how to connect the signals; timing and loading have not been analyzed. In addition, not all bypass capacitors are shown.

Figure 11-11. Example Schematic for Muxed Host-Bus 16 Mode

### 11.4.3.4 Speed of Transactions

The **COUNT0** field in the **EPIBAUD** register must be configured to set the main transaction rate based on what the slave device can support (including wiring considerations). The main control transitions are normally  $\frac{1}{2}$  the baud rate (**COUNT0** = 1) because the EPI block forces data versus control to change on alternating clocks. When using dual chip selects, each chip select can access the bus using differing baud rates by setting the **CSBAUD** bit in the **EPIHBnCFG2** register. In this case, the **COUNT0** field controls the **CS0n** transactions, and the **COUNT1** field controls the **CS1n** transactions. When using quad chip select mode, the **COUNT0** bit field of the **EPIBAUD2** register

controls the baud rate of CS2n and the COUNT1 bit field is programmed to control the baud rate of CS3n.

Additionally, the Host-Bus mode provides read and write wait states for the data portion to support different classes of device. These wait states stretch the data period (hold the rising edge of data strobe) and may be used in all four sub-modes. The wait states are set using the WRWS and RDWS bits in the **EPI Host-Bus n Configuration (EPIHBnCFGn)** register. The WRWS and RDWS bits are enhanced with more precision by WRWSM and RDWSM bits in the **EPIHBnTIMEn** registers. Note none of the wait state configuration bits can be set concurrently with the BURST bit in the same **EPIHBnCFGn** register. See Table 11-11 on page 835 for programming information.

**Table 11-11. Data Phase Wait State Programming**

| RDWS or WRWS Encoding in EPIHBnCFGn Register | RDWSM or WRWSM Encoding in EPIHBnTIMEn Registers | Data Phase Wait States |
|--|--|------------------------|
| 0x0  | 1  | 1 EPI clocks           |
| 0x0  | 0  | 2 EPI clocks           |
| 0x1  | 1  | 3 EPI clocks           |
| 0x1  | 0  | 4 EPI clocks           |
| 0x2  | 1  | 5 EPI clocks           |
| 0x2  | 0  | 6 EPI clocks           |
| 0x3  | 1  | 7 EPI clocks           |
| 0x3  | 0  | 8 EPI clocks           |

The CAPWIDTH bit in **EPIHBnTIMEn** registers controls the delay between Host-Bus transfers. When the CSBAUD bit is set and multi-chip selects have been configured in the **EPIHBnCFG2** registers, delay takes an additional clock cycle to adjust the clock rate of different chip selects.

Word read and write transactions can be enhanced through the enabling of the BURST bit in the **EPIHB16CFGn** registers.

#### 11.4.3.5 Sub-Modes of Host Bus 8/16

The EPI controller supports four variants of the Host-Bus model using 8 or 16 bits of data in all four cases. The four sub-modes are selected using the MODE bits in the **EPIHBnCFG** register, and are:

1. Address and data are muxed. This scheme is used by many 8051 devices, some Microchip PIC parts, and some ATmega parts. When used for standard SRAMs, a latch must be used between the microcontroller and the SRAM. This sub-mode is provided for compatibility with existing devices that support data transfers without a latch (that is, CPLDs). In general, the de-muxed sub-mode should normally be used. The ALE configuration should be used in this mode, as all Host-Bus accesses have an address phase followed by a data phase. The ALE indicates to an external latch to capture the address then hold until the data phase. The ALE configuration is controlled by configuring the CSCFG and CSCFGEXT field to be 0x0 in the **EPIHBnCFG2** register. The ALE can be enhanced to access two or four external devices with four separate CSn signals. By configuring the CSCFG field to be 0x3 and the CSCFGEXT bit to be 0 in the **EPIHBnCFG2** register, EPI0S30 functions as ALE, EPI0S27 functions as CS1n, and EPI0S26 functions as CS0n. When the CSCFG field is set to 0x0 and the CSCFGEXT bit is set to 1 in the **EPIHBnCFG2** register, EPI0S30 functions as ALE, EPI0S33 functions as CS3n, EPI0S34 functions as CS2n, EPI0S27 functions as CS1n, and EPI0S26 functions as CS0n. The CSn is best used for Host-Bus unmuxed mode, in which EPI address and data pins are separate. The CSn indicates when the address and data phases of a read or write access are occurring.

2. Address and data are separate with 8 or 16 bits of data and up to 20 bits of address (1 MB). This scheme is used by more modern 8051 devices, as well as some PIC and ATmega parts. This mode is generally used with SRAMs in continuous read modes, many EEPROMs, and many NOR Flash memory devices. Note that there is no hardware command write support for Flash memory devices; this mode should only be used for Flash memory devices programmed at manufacturing time. If a Flash memory device must be written and does not support a direct programming model, the command mechanism must be performed in software. The CSn configuration should be used in this mode. The CSn signal indicates when the address and data phases of a read or write access is occurring. The CSn configuration is controlled by configuring the `CSCFG` field to be 0x1 and the `CSCFGEXT` bit to be 0 in the **EPIHBnCFG2** register.
3. Continuous read mode where address and data are separate. This read sub-mode is used by some SRAMs and can read more quickly by only changing the address (and not using RDn/OEn strobing). In this sub-mode, reads are performed by keeping the read mode selected (output enable is asserted) and then changing the address pins. The data pins are changed by the SRAM after the address pins change. For example, to read data from address 0x100 and then 0x101, the EPI controller asserts the output-enable signal and then configures the address pins to 0x100; the EPI controller then captures what is on the data pins and increments A0 to 1 (so the address is now 0x101); the EPI controller then captures what is on the data pins. Note that this mode consumes higher power because the SRAM must continuously drive the data pins. This mode is not practical in HB16 mode for normal SRAMs because there are generally not enough address bits available. Writes are not permitted in this mode.
4. FIFO mode uses 8 or 16 bits of data, removes ALE and address pins and optionally adds external XFIFO FULL/EMPTY flag inputs. This scheme is used by many devices, such as radios, communication devices (including USB2 devices), and some FPGA configurations (FIFO through block RAM). This sub-mode provides the data side of the normal Host-Bus interface, but is paced by the FIFO control signals. It is important to consider that the XFIFO FULL/EMPTY control signals may stall the interface and could have an impact on blocking read latency from the processor or  $\mu$ DMA. Note that the EPI FIFO can only be used in asynchronous mode.

For the three modes above (1, 2, 4) that the Host-Bus 16 mode supports, byte select signals can be optionally implemented by setting the `BSEL` bit in the **EPIHB16CFG** register.

**Note:** Byte accesses should not be attempted if the `BSEL` bit has not been enabled in Host-Bus 16 Mode.

See “External Peripheral Interface (EPI)” on page 1740 for timing details for the Host-Bus mode.

### 11.4.3.6 Bus Operation

Bus operation is the same in Host-Bus 8 and Host-Bus 16 modes and is asynchronous. Timing diagrams show both ALE and CSn operation. The optional HB16 byte select signals have the same timing as the address signals. If wait states are required in the bus access, they can be inserted during the data phase of the access using the `WRWS` and `RDWS` bits in the **EPIHBnCFG2** register. Each wait state adds 2 EPI clock cycles to the duration of the WRn or RDn strobe. During idle cycles, the address and muxed address data signals maintain the state of the last cycle.

Figure 11-12 on page 837 shows a basic Host-Bus read cycle. Figure 11-13 on page 837 shows a basic Host-Bus write cycle. Both of these figures show address and data signals in the non-multiplexed mode (`MODE` field is 0x1 in the **EPIHBnCFG** register).

**Figure 11-12. Host-Bus Read Cycle, MODE = 0x1, WRHIGH = 0, RDHIGH = 0**

<sup>a</sup> BSEL0n and BSEL1n are available in Host-Bus 16 mode only.

**Figure 11-13. Host-Bus Write Cycle, MODE = 0x1, WRHIGH = 0, RDHIGH = 0**

<sup>a</sup> BSEL0n and BSEL1n are available in Host-Bus 16 mode only.

Figure 11-14 on page 838 shows a write cycle with the address and data signals multiplexed (MODE field is 0x0 in the **EPIHBnCFG** register). A read cycle would look similar, with the RDn strobe being asserted along with CSn and data being latched on the rising edge of RDn.

**Figure 11-14. Host-Bus Write Cycle with Multiplexed Address and Data, MODE = 0x0, WRHIGH = 0, RDHIGH = 0**

<sup>a</sup> BSEL0n and BSEL1n are available in Host-Bus 16 mode only.

When using ALE with dual CSn configuration (CSCFGEXT bit is 0 and the CSCFG field is 0x3 in the **EPIHBnCFG2** register) or quad chip select (CSCFGEXT bit is 1 and CSCSFG is 0x2), the appropriate CSn signal is asserted at the same time as ALE, as shown in Figure 11-15 on page 838.

**Figure 11-15. Host-Bus Write Cycle with Multiplexed Address and Data and ALE with Dual or Quad CSn**

<sup>a</sup> BSEL0n and BSEL1n are available in Host-Bus 16 mode only.

Figure 11-16 on page 838 shows continuous read mode accesses. In this mode, reads are performed by keeping the read mode selected (output enable is asserted) and then changing the address pins. The data pins are changed by the SRAM after the address pins change.

**Figure 11-16. Continuous Read Mode Accesses**

FIFO mode accesses are the same as normal read and write accesses, except that the ALE signal and address pins are not present. Two input signals can be used to indicate when the XFIFO is full or empty to gate transactions and avoid overruns and underruns. The FFULL and FEMPTY signals are synchronized and must be recognized as asserted by the microcontroller for 2 system clocks before they affect transaction status. The MAXWAIT field in the **EPIHBnCFG** register defines the maximum number of EPI clocks to wait while the FEMPTY or FFULL signal is holding off a transaction. Figure 11-17 on page 839 shows how the FEMPTY signal should respond to a write and read from the XFIFO. Figure 11-18 on page 839 shows how the FEMPTY and FFULL signals should respond to 2 writes and 1 read from an external FIFO that contains two entries.

**Figure 11-17. Write Followed by Read to External FIFO**

**Figure 11-18. Two-Entry FIFO**

#### 11.4.4 General-Purpose Mode

The **General-Purpose Mode Configuration (EPIGPCFG)** register is used to configure the control, data, and address pins, if used. Any unused EPI controller signals can be used as GPIOs or another alternate function. The general-purpose configuration can be used for custom interfaces with FPGAs, CPLDs, and digital data acquisition and actuator control.

General-Purpose mode is designed for three general types of use:

- Extremely high-speed clocked interfaces to FPGAs and CPLDs. Three sizes of data and optional address are supported. Framing and clock-enable functions permit more optimized interfaces.
- General parallel GPIO. From 1 to 32 pins may be written or read, with the speed precisely controlled by the **EPIBAUD** register baud rate (when used with the WFIFO and/or the NBRFIFO) or by the rate of accesses from software or  $\mu$ DMA. Examples of this type of use include:

- Reading 20 sensors at fixed time periods by configuring 20 pins to be inputs, configuring the `COUNT0` field in the **EPIBAUD** register to some divider, and then using non-blocking reads.
- Implementing a very wide ganged PWM/PCM with fixed frequency for driving actuators, LEDs, etc.
- General custom interfaces of any speed.

The configuration allows for choice of an output clock (free-running or gated), a framing signal (with frame size), a ready input (to stretch transactions), an address (of varying sizes), and data (of varying sizes). Additionally, provisions are made for separating data and address phases.

The interface has the following optional features:

- Use of the EPI clock output is controlled by the `CLKPIN` bit in the **EPIGPCFG** register. Unclocked uses include general-purpose I/O and asynchronous interfaces (optionally using RD and WR strobes). Clocked interfaces allow for higher speeds and are much easier to connect to FPGAs and CPLDs (which usually include input clocks).
- EPI clock, if used, may be free running or gated depending on the `CLKGATE` bit in the **EPIGPCFG** register. A free-running EPI clock requires another method for determining when data is live, such as the frame pin or RD/WR strobes. A gated clock approach uses a setup-time model in which the EPI clock controls when transactions are starting and stopping. The gated clock is held high until a new transaction is started and goes high at the end of the cycle where RD/WR/FRAME and address (and data if write) are emitted.
- Use of the RD and WR outputs is controlled by the `RW` bit in the **EPIGPCFG** register. For interfaces where the direction is known (in advance, related to frame size, or other means), these strobes are not needed. For most other interfaces, RD and WR are used so the external peripheral knows what transaction is taking place, and if any transaction is taking place.
- Separation of address/request and data phases may be used on writes using the `WR2CYC` bit in the **EPIGPCFG** register. This configuration allows the external peripheral extra time to act. Address and data phases must be separated on reads. When configured to use an address as specified by the `ASIZE` field in the **EPIGPCFG** register, the address is emitted on the with the RD strobe (first cycle) and data is expected to be returned on the next cycle (when RD is not asserted). If no address is used, then RD is asserted on the first cycle and data is captured on the second cycle (when RD is not asserted), allowing more setup time for data.

**Note:** When `WR2CYC = 0`, write data is valid when the WR strobe is asserted (High). When `WR2CYC = 1`, write data is valid when the WR strobe is Low after being asserted (High).

For writes, the output may be in one or two cycles. In the two-cycle case, the address (if any) is emitted on the first cycle with the WR strobe and the data is emitted on the second cycle (with WR not asserted). Although split address and write data phases are not normally needed for logic reasons, it may be useful to make read and write timings match. If 2-cycle reads or writes are used, the `RW` bit is automatically set.

- Address may be emitted (controlled by the `ASIZE` field in the **EPIGPCFG** register). The address may be up to 4 bits (16 possible values), up to 12 bits (4096 possible values), or up to 20 bits (1 M possible values). Size of address limits size of data, for example, 4 bits of address support up to 24 bits data. 4-bit address uses `EPIOS[27:24]`; 12-bit address uses `EPIOS[27:16]`; 20-bit address uses `EPIOS[27:8]`. The address signals may be used by the external peripheral as an address, code (command), or for other unrelated uses (such as a chip enable). If the chosen address/data combination does not use all of the EPI signals, the unused pins can be

used as GPIOs or for other functions. For example, when using a 4-bit address with an 8-bit data, the pins assigned to `EPI0S[23:8]` can be assigned to other functions.

- Data may be 8 bits, 16 bits, 24 bits, or 32 bits (controlled by the `DSIZE` field in the **EPIGPCFG** register). By default, the EPI controller uses data bits [7:0] when the `DSIZE` field in the **EPIGPCFG** register is 0x0; data bits [15:0] when the `DSIZE` field is 0x1; data bits [23:0] when the `DSIZE` field is 0x2; and data bits [31:0] when the `DSIZE` field is 0x3. 32-bit data cannot be used with address or EPI clock or any other signal. 24-bit data can only be used with 4-bit address or no address.
- When using the EPI controller as a GPIO interface, writes are FIFOed (up to 4 can be held at any time), and up to 32 pins are changed using the **EPIBAUD** clock rate specified by `COUNT0`. As a result, output pin control can be very precisely controlled as a function of time. By contrast, when writing to normal GPIOs, writes can only occur 8-bits at a time and take up to two clock cycles to complete. In addition, the write itself may be further delayed by the bus due to  $\mu$ DMA or draining of a previous write. With both GPIO and the EPI controller, reads may be performed directly, in which case the current pin states are read back. With the EPI controller, the non-blocking interface may also be used to perform reads based on a fixed time rule via the **EPIBAUD** clock rate.

Table 11-12 on page 841 shows how the `EPI0S[31:0]` signals function while in General-Purpose mode. Notice that the address connections vary depending on the data-width restrictions of the external peripheral.

**Table 11-12. EPI General-Purpose Signal Connections**

| EPI Signal | General-Purpose Signal (D8, A20) | General- Purpose Signal (D16, A12) | General- Purpose Signal (D24, A4) | General- Purpose Signal (D32) |
|------------|----------------------------------|------------------------------------|-----------------------------------|-------------------------------|
| EPI0S0     | D0                               | D0                                 | D0                                | D0                            |
| EPI0S1     | D1                               | D1                                 | D1                                | D1                            |
| EPI0S2     | D2                               | D2                                 | D2                                | D2                            |
| EPI0S3     | D3                               | D3                                 | D3                                | D3                            |
| EPI0S4     | D4                               | D4                                 | D4                                | D4                            |
| EPI0S5     | D5                               | D5                                 | D5                                | D5                            |
| EPI0S6     | D6                               | D6                                 | D6                                | D6                            |
| EPI0S7     | D7                               | D7                                 | D7                                | D7                            |
| EPI0S8     | A0                               | D8                                 | D8                                | D8                            |
| EPI0S9     | A1                               | D9                                 | D9                                | D9                            |
| EPI0S10    | A2                               | D10                                | D10                               | D10                           |
| EPI0S11    | A3                               | D11                                | D11                               | D11                           |
| EPI0S12    | A4                               | D12                                | D12                               | D12                           |
| EPI0S13    | A5                               | D13                                | D13                               | D13                           |
| EPI0S14    | A6                               | D14                                | D14                               | D14                           |

| EPI0S16    | A8                               | A0 <sup>a</sup>                    | D16                               | D16                           |
| EPI0S17    | A9                               | A1                                 | D17                               | D17                           |
| EPI0S18    | A10                              | A2                                 | D18                               | D18                           |
| EPI0S19    | A11                              | A3                                 | D19                               | D19                           |
| EPI0S20    | A12                              | A4                                 | D20                               | D20                           |

**Table 11-12. EPI General-Purpose Signal Connections (continued)**

| EPI Signal | General-Purpose Signal (D8, A20) | General- Purpose Signal (D16, A12) | General- Purpose Signal (D24, A4) | General- Purpose Signal (D32) |
|------------|----------------------------------|------------------------------------|-----------------------------------|-------------------------------|
| EPI0S21    | A13                              | A5                                 | D21                               | D21                           |
| EPI0S22    | A14                              | A6                                 | D22                               | D22                           |
| EPI0S23    | A15                              | A7                                 | D23                               | D23                           |
| EPI0S24    | A16                              | A8                                 | A0 <sup>b</sup>                   | D24                           |
| EPI0S25    | A17                              | A9                                 | A1                                | D25                           |
| EPI0S26    | A18                              | A10                                | A2                                | D26                           |
| EPI0S27    | A19                              | A11                                | A3                                | D27                           |
| EPI0S28    | WR                               | WR                                 | WR                                | D28                           |
| EPI0S29    | RD                               | RD                                 | RD                                | D29                           |
| EPI0S30    | Frame                            | Frame                              | Frame                             | D30                           |
| EPI0S31    | Clock                            | Clock                              | Clock                             | D31                           |

a. In this mode, half-word accesses are used. AO is the LSB of the address and is equivalent to the system A1 address.

b. In this mode, word accesses are used. AO is the LSB of the address and is equivalent to the system A2 address.

### 11.4.4.1 Bus Operation

A basic access is 1 EPI clock for write cycles and 2 EPI clocks for read cycles. An additional EPI clock can be inserted into a write cycle by setting the **WR2CYC** bit in the **EPIGPCFG** register.

**Figure 11-19. Single-Cycle Single Write Access, FRM50=0, FRMCNT=0, WR2CYC=0**

**Figure 11-20. Two-Cycle Read, Write Accesses, FRM50=0, FRMCNT=0, WR2CYC=1****Figure 11-21. Read Accesses, FRM50=0, FRMCNT=0****FRAME Signal Operation**

The operation of the FRAME signal is controlled by the FRMCNT and FRM50 bits. When FRM50 is clear, the FRAME signal is high whenever the WR or RD strobe is high. When FRMCNT is clear, the FRAME signal is simply the logical OR of the WR and RD strobes so the FRAME signal is high during every read or write access, see Figure 11-22 on page 844.

**Figure 11-22. FRAME Signal Operation, FRM50=0 and FRMCNT=0**

If the `FRMCNT` field is `0x1`, then the `FRAME` signal pulses high during every other read or write access, see Figure 11-23 on page 844.

**Figure 11-23. FRAME Signal Operation, FRM50=0 and FRMCNT=1**

If the `FRMCNT` field is `0x2` and `FRM50` is clear, then the `FRAME` signal pulses high during every third access, and so on for every value of `FRMCNT`, see Figure 11-24 on page 844.

**Figure 11-24. FRAME Signal Operation, FRM50=0 and FRMCNT=2**

When `FRM50` is set, the `FRAME` signal transitions on the rising edge of either the `WR` or `RD` strobes. When `FRMCNT=0`, the `FRAME` signal transitions on the rising edge of `WR` or `RD` for every access, see Figure 11-25 on page 844.

**Figure 11-25. FRAME Signal Operation, FRM50=1 and FRMCNT=0**

When `FRMCNT=1`, the `FRAME` signal transitions on the rising edge of the `WR` or `RD` strobes for every other access, see Figure 11-26 on page 845.

**Figure 11-26. FRAME Signal Operation, FRM50=1 and FRMCNT=1**

When  $FRMCNT=2$ , the FRAME signal transitions the rising edge of the WR or RD strobes for every third access, and so on for every value of  $FRMCNT$ , see Figure 11-27 on page 845.

**Figure 11-27. FRAME Signal Operation, FRM50=1 and FRMCNT=2**

### **EPI Clock Operation**

If the  $CLKGATE$  bit in the **EPIGPCFG** register is clear, the EPI clock always toggles when General-purpose mode is enabled. If  $CLKGATE$  is set, the clock is output only when a transaction is occurring, otherwise the clock is held high. If the  $WR2CYC$  bit is clear, the EPI clock begins toggling 1 cycle before the WR strobe goes High. If the  $WR2CYC$  bit is set, the EPI clock begins toggling when the WR strobe goes High. The clock stops toggling after the first rising edge after the WR strobe is deasserted. The RD strobe operates in the same manner as the WR strobe when the  $WR2CYC$  bit is set. See Figure 11-28 on page 845 and Figure 11-29 on page 846.

**Figure 11-28. EPI Clock Operation, CLKGATE=1, WR2CYC=0**

Figure 11-29. EPI Clock Operation, CLKGATE=1, WR2CYC=1

## 11.5 Register Map

Table 11-13 on page 846 lists the EPI registers. The offset listed is a hexadecimal increment to the register's address, relative to the base address of 0x400D.0000. Note that the EPI controller clock must be enabled before the registers can be programmed (see page 384). There must be a delay of 3 system clocks after the EPI module clock is enabled before any EPI module registers are accessed.

**Note:** A write immediately followed by a read of the same register, may not return correct data. A delay (instruction or NOP) must be inserted between the write and the read for correct operation. Read-write does not have this issue, so use of read-write for clear of error interrupt cause is not affected.

**Note:** For all versions of EPI, only WORD read and write accesses to registers are supported.

Table 11-13. External Peripheral Interface (EPI) Register Map

| Offset | Name        | Type | Reset       | Description                       | See page |
|--------|-------------|------|-------------|-----------------------------------|----------|
| 0x000  | EPICFG      | RW   | 0x0000.0000 | EPI Configuration                 | 849      |
| 0x004  | EPIBAUD     | RW   | 0x0000.0000 | EPI Main Baud Rate                | 851      |
| 0x008  | EPIBAUD2    | RW   | 0x0000.0000 | EPI Main Baud Rate                | 853      |
| 0x010  | EPISDRAMCFG | RW   | 0x82EE.0000 | EPI SDRAM Configuration           | 855      |
| 0x010  | EPIHB8CFG   | RW   | 0x0008.FF00 | EPI Host-Bus 8 Configuration      | 857      |
| 0x010  | EPIHB16CFG  | RW   | 0x0008.FF00 | EPI Host-Bus 16 Configuration     | 862      |
| 0x010  | EPIGPCFG    | RW   | 0x0000.0000 | EPI General-Purpose Configuration | 868      |
| 0x014  | EPIHB8CFG2  | RW   | 0x0008.0000 | EPI Host-Bus 8 Configuration 2    | 871      |
| 0x014  | EPIHB16CFG2 | RW   | 0x0008.0000 | EPI Host-Bus 16 Configuration 2   | 877      |

## **11.6 Register Descriptions**

This section lists and describes the EPI registers, in numerical order by address offset.

## Register 1: EPI Configuration (EPICFG), offset 0x000

**Important:** The `MODE` field determines which configuration register is accessed for offsets 0x010 and 0x014. Any write to the `EPICFG` register resets the register contents at offsets 0x010 and 0x014.

The configuration register is used to enable the block, select a mode, and select the basic pin use (based on the mode). Note that attempting to program an undefined `MODE` field clears the `BLKEN` bit and disables the EPI controller.

**Register 2: EPI Main Baud Rate (EPIBAUD), offset 0x004**

The system clock is used internally to the EPI Controller. The baud rate counter can be used to divide the system clock down to control the speed on the external interface. If the mode selected emits an external EPI clock, this register defines the EPI clock emitted. If the mode selected does not use an EPI clock, this register controls the speed of changes on the external interface. Care must be taken to program this register properly so that the speed of the external bus corresponds to the speed of the external peripheral and puts acceptable current load on the pins. `COUNT0` is the bit field used in all modes except in HB8 and HB16 modes with dual chip selects and quad chip selects when different baud rates are selected, see page 871 and page 877. If different baud rates are used, `COUNT0` is associated with the address range specified by `CS0n` and `COUNT1` is associated with the address range specified by `CS1`. The **EPIBAUD2** register configures the baud rates for `CS2n` and `CS3n`.

The `COUNTn` field is not a straight divider or count. The EPI Clock on `EPI0S31` is related to the `COUNTn` field and the system clock as follows:

If `COUNTn = 0`,

$$EPIClockFreq = SystemClockFreq$$

otherwise:

$$EPIClockFreq = \frac{SystemClockFreq}{\left(\left\lfloor \frac{COUNTn}{2} \right\rfloor + 1\right) \times 2}$$

where the symbol around `COUNTn/2` is the floor operator, meaning the largest integer less than or equal to `COUNTn/2`.

So, for example, a `COUNTn` of 0x0001 results in a clock rate of 1/2(system clock); a `COUNTn` of 0x0002 or 0x0003 results in a clock rate of 1/4(system clock).

The baud rate counter can also be configured as an integer divide by enabling `INTDIV` in the **EPICFG** register. When enabled, `COUNTn` of 0x0000 or 0x0001 results in a clock rate equal to system clock. `COUNTn` of 0x0002 results in a clock rate of 1/2 (system clock). `COUNTn` of 0x0003 results in a clock rate of 1/3 (system clock).

### Register 3: EPI Main Baud Rate (EPIBAUD2), offset 0x008

The system clock is used internally to the EPI Controller. The baud rate counter can be used to divide the system clock down to control the speed on the external interface. If the mode selected emits an external EPI clock, this register defines the EPI clock emitted. If the mode selected does not use an EPI clock, this register controls the speed of changes on the external interface. Care must be taken to program this register properly so that the speed of the external bus corresponds to the speed of the external peripheral and puts acceptable current load on the pins. COUNT0 and COUNT1 are used in quad chip select mode when different baud rates are selected, page 871 or page 877. If different baud rates are used, COUNT0 is associated with the address range specified by CS2n and COUNT1 is associated with the address range specified by CS3n.

The COUNTn field is not a straight divider or count. The EPI Clock on EPI0S31 is related to the COUNTn field and the system clock as follows:

If COUNTn = 0,

$$EPIClockFreq = SystemClockFreq$$

otherwise:

$$EPIClockFreq = \frac{SystemClockFreq}{\left(\left\lfloor \frac{COUNTn}{2} \right\rfloor + 1\right) \times 2}$$

where the symbol around COUNTn/2 is the floor operator, meaning the largest integer less than or equal to COUNTn/2.

So, for example, a COUNTn of 0x0001 results in a clock rate of 1/2(system clock); a COUNTn of 0x0002 or 0x0003 results in a clock rate of 1/4(system clock).

## Register 4: EPI SDRAM Configuration (EPISDRAMCFG), offset 0x010

**Important:** The `MODE` field in the `EPICFG` register determines which configuration register is accessed for offsets 0x010 and 0x014.

To access `EPISDRAMCFG`, the `MODE` field must be 0x1.

The SDRAM Configuration register is used to specify several parameters for the SDRAM controller. Note that this register is reset when the `MODE` field in the `EPICFG` register is changed. If another mode is selected and the SDRAM mode is selected again, the values must be reinitialized.

The SDRAM interface is designed to interface to x16 SDR SDRAMs of 64 MHz or higher, with the address and data pins overlapped (wire ORed on the board). See Table 11-3 on page 815 for pin assignments.

## Register 5: EPI Host-Bus 8 Configuration (EPIHB8CFG), offset 0x010

**Important:** The `MODE` field in the `EPICFG` register determines which configuration register is accessed for offsets 0x010 and 0x014.

To access `EPIHB8CFG`, the `MODE` field must be 0x2.

The Host Bus 8 Configuration register is activated when the HB8 mode is selected. The HB8 mode supports muxed address/data (overlay of lower 8 address and all 8 data pins), separate address/data, and address-less FIFO mode. Note that this register is reset when the `MODE` field in the `EPICFG` register is changed. If another mode is selected and the HB8 mode is selected again, the values must be reinitialized.

This mode is intended to support SRAMs, Flash memory (read), FIFOs, CPLDs/FPGAs, and devices with an MCU/HostBus slave or 8-bit FIFO interface support.

Refer to Table 11-8 on page 823 for information on signal configuration controlled by this register and the `EPIHB8CFG2` register.

If less address pins are required, the corresponding `AFSEL` bit (page 762) should not be enabled so the EPI controller does not drive those pins, and they are available as standard GPIOs.

EPI Host-Bus 8 Mode can be configured to use one to four chip selects with and without the use of ALE. If an alternative to chip selects are required, a chip enable can be handled in one of three ways:

1. Manually control via GPIOs.
2. Associate one or more upper address pins to CE. Because CE is normally CEn, lower addresses are not used. For example, if pins `EPI0S27` and `EPI0S26` are used for Device 1 and 0 respectively, then address 0x6800.0000 accesses Device 0 (Device 1 has its CEn high), and 0x6400.0000 accesses Device 1 (Device 0 has its CEn high). The pull-up behavior on the corresponding GPIOs must be properly configured to ensure that the pins are disabled when the interface is not in use.
3. With certain SRAMs, the ALE can be used as CEn because the address remains stable after the ALE strobe. The subsequent `WRn` or `RDn` signals write or read when ALE is low thus providing CEn functionality.

**Register 6: EPI Host-Bus 16 Configuration (EPIHB16CFG), offset 0x010**

**Important:** The `MODE` field in the `EPICFG` register determines which configuration register is accessed for offsets 0x010 and 0x014.

To access `EPIHB16CFG`, the `MODE` field must be 0x3.

The Host Bus 16 sub-configuration register is activated when the HB16 mode is selected. The HB16 mode supports muxed address/data (overlay of lower 16 address and all 16 data pins), separated address/data, and address-less FIFO mode. Note that this register is reset when the `MODE` field in the `EPICFG` register is changed. If another mode is selected and the HB16 mode is selected again, the values must be reinitialized.

This mode is intended to support SRAMs, Flash memory (read), FIFOs, and CPLDs/FPGAs, and devices with an MCU/HostBus slave or 16-bit FIFO interface support.

Refer to Table 11-9 on page 825 for information on signal configuration controlled by this register and the `EPIHB16CFG2` register.

If less address pins are required, the corresponding `AFSEL` bit (page 762) should not be enabled so the EPI controller does not drive those pins, and they are available as standard GPIOs.

EPI Host-Bus 16 Mode can be configured to use one to four chip selects with and without the use of ALE. If an alternative to chip selects are required, a chip enable can be handled in one of three ways:

1. Manually control via GPIOs.
2. Associate one or more upper address pins to CE. Because CE is normally CEn, lower addresses are not used. For example, if pins `EPI0S27` and `EPI0S26` are used for Device 1 and 0 respectively, then address 0x6800.0000 accesses Device 0 (Device 1 has its CEn high), and 0x6400.0000 accesses Device 1 (Device 0 has its CEn high). The pull-up behavior on the corresponding GPIOs must be properly configured to ensure that the pins are disabled when the interface is not in use.
3. With certain SRAMs, the ALE can be used as CEn because the address remains stable after the ALE strobe. The subsequent `WRn` or `RDn` signals write or read when ALE is low thus providing CEn functionality.

See Table 11-9 on page 825 for details on which EPI signals are used.</p> <p><b>Note:</b> If BSEL = 0, byte accesses cannot be executed.</p>   |

| Bit/Field | Name | Type | Reset | Description   |
|-----------|------|------|-------|---|
| 1:0       | MODE | RW   | 0x0   | <p>Host Bus Sub-Mode</p> <p>This field determines which of three Host Bus 16 sub-modes to use. Sub-mode use is determined by the connected external peripheral. See Table 11-9 on page 825 for information on how this bit field affects the operation of the EPI signals. When used with multiple chip select option and the CSBAUD bit is set to 1 in the <b>EPIHB16CFG2</b> register, this configuration is for CS0n. If the multiple chip select option is enabled and CSBAUD is clear, all chip-selects use the MODE encoding programmed in this register.</p> <p>Value Description</p> <p>0x0 ADMUX – AD[15:0]<br/>Data and Address are muxed.</p> <p>0x1 ADNONMUX – D[15:0]<br/>Data and address are separate. This mode is not practical in HB16 mode for normal peripherals because there are generally not enough address bits available.</p> <p>0x2 Continuous Read - D[15:0]<br/>This mode is the same as ADNONMUX, but uses address switch for multiple reads instead of OEn strobing. This mode is not practical in HB16 mode for normal SRAMs because there are generally not enough address bits available.</p> <p>0x3 XFIFO – D[15:0]<br/>This mode adds XFIFO controls with sense of XFIFO full and XFIFO empty. This mode uses no address or ALE.<br/>Note that the XFIFO can only be used in asynchronous mode.</p> |

## Register 7: EPI General-Purpose Configuration (EPIGPCFG), offset 0x010

**Important:** The `MODE` field in the `EPICFG` register determines which configuration register is accessed for offsets 0x010 and 0x014.

To access `EPIGPCFG`, the `MODE` field must be 0x0.

The General-Purpose configuration register is used to configure the control, data, and address pins. This mode can be used for custom interfaces with FPGAs, CPLDs, and for digital data acquisition and actuator control. Note that this register is reset when the `MODE` field in the `EPICFG` register is changed. If another mode is selected and the General-purpose mode is selected again, the register the values must be reinitialized.

This mode is designed for 3 general types of use:

- Extremely high-speed clocked interfaces to FPGAs and CPLDs, with 3 sizes of data and optional address. Framing and clock-enable permit more optimized interfaces.
- General parallel GPIO. From 1 to 32 pins may be written or read, with the speed precisely controlled by the baud rate in the `EPIBAUD` register (when used with the `NBRFIFO` and/or the `WFIFO`) or by rate of accesses from software or  $\mu$ DMA.
- General custom interfaces of any speed.

The configuration allows for choice of an output clock (free running or gated), a framing signal (with frame size), a ready input (to stretch transactions), read and write strobes, address of varying sizes, and data of varying sizes. Additionally, provisions are made for splitting address and data phases on the external interface.

## Register 8: EPI Host-Bus 8 Configuration 2 (EPIHB8CFG2), offset 0x014

**Important:** The `MODE` field in the `EPICFG` register determines which configuration register is accessed for offsets 0x010 and 0x014.

To access `EPIHB8CFG2`, the `MODE` field of the `EPICFG` register must be 0x2.

This register is used to configure operation while in Host-Bus 8 mode. Note that this register is reset when the `MODE` field in the `EPICFG` register is changed. If another mode is selected and the Host-Bus 8 mode is selected again, the values must be reinitialized.

| 27        | CSCFGEXT | RW   | 0     | <p>Chip Select Extended Configuration</p> <p>This field is used in conjunction with <code>CSCFG</code>, to extend the chip select options, and ALE format. The values 0x0 through 0x3 are from the <code>CSCFG</code> field. The <code>CSCFGEXT</code> bit extends the values to 0x7.</p> |

Value Description

- 0 `CSCFG` bit field is used in chip select configuration.
- 1 The `CSCFG` bit field is extended with `CSCFGEXT` representing the MSB.

The possible chip select configurations when the `CSCFGEXT` bit is enabled are shown below:

**Table 11-14. CSCFGEXT + CSCFG Encodings**

| Value | Description   |
|-------|---|
| 0x0   | <p>ALE Configuration</p> <p><code>EPI0S30</code> is used as an address latch (ALE). The ALE signal is generally used when the address and data are muxed (<code>MODE</code> field in the <code>EPIHB8CFG</code> register is 0x0). The ALE signal is used by an external latch to hold the address through the bus cycle.</p>  |
| 0x1   | <p>CSn Configuration</p> <p><code>EPI0S30</code> is used as a Chip Select (CSn). When using this mode, the address and data are generally not muxed (<code>MODE</code> field in the <code>EPIHB8CFG</code> register is 0x1). However, if address and data muxing is needed, the <code>WR</code> signal (<code>EPI0S29</code>) and the <code>RD</code> signal (<code>EPI0S28</code>) can be used to latch the address when CSn is low.</p> |
| 0x2   | <p>Dual CSn Configuration</p> <p><code>EPI0S30</code> is used as CS0n and <code>EPI0S27</code> is used as CS1n. Whether CS0n or CS1n is asserted is determined by the most significant address bit for a respective external address map. This configuration can be used for a RAM bank split between 2 devices as well as when using both an external RAM and an external peripheral.</p>  |
| 0x3   | <p>ALE with Dual CSn Configuration</p> <p><code>EPI0S30</code> is used as address latch (ALE), <code>EPI0S27</code> is used as CS1n, and <code>EPI0S26</code> is used as CS0n. Whether CS0n or CS1n is asserted is determined by the most significant address bit for a respective external address map.</p>  |
| 0x4   | <p>ALE with Single CSn Configuration</p> <p><code>EPI0S30</code> is used as address latch (ALE) and <code>EPI0S27</code> is used as CSn.</p>  |
| 0x5   | <p>Quad CSn Configuration</p> <p><code>EPI0S30</code> is used as CS0n and <code>EPI0S27</code> is used as CS1n. <code>EPI0S34</code> is used as CS2n and <code>EPI0S33</code> is used as CS3n.</p>  |
| 0x6   | <p>ALE with Quad CSn Configuration</p> <p><code>EPI0S30</code> is used as ALE, <code>EPI0S26</code> is CS0n, and <code>EPI0S27</code> is used as CS1n. <code>EPI0S34</code> is used as CS2n and <code>EPI0S33</code> is used as CS3n.</p>   |
| 0x7   | Reserved  |

| Bit/Field | Name   | Type | Reset | Description   |
|-----------|--------|------|-------|---|
| 26        | CSBAUD | RW   | 0     | <p>Chip Select Baud Rate and Multiple Sub-Mode Configuration enable</p> <p>This bit is only valid when the <code>CSCFGEXT + CSCFG</code> field is programmed to 0x2 or 0x3, 0x5 or 0x6. This bit configures the baud rate settings for CS0n, CS1n, CS2n, and CS3n.</p> <p>This bit must also be set to allow different sub-mode configurations on chip-selects. If this bit is clear, all chip-select sub-modes are based on the <code>MODE</code> encoding defined in the <code>EPI8HBCFG</code> register.</p> <p>If the <code>CSBAUD</code> bit is set in the <code>EPIHBnCFG2</code> register and dual- or quad-chip selects are enabled, then the individual chip selects can use different clock frequencies, wait states and strobe polarity.</p> <p>Value Description</p> <p>0 Same Baud Rate and Same Sub-Mode<br/>All CSn use the baud rate for the external bus that is defined by the <code>COUNT0</code> field in the <code>EPIBAUD</code> register and the sub-mode programmed in the <code>MODE</code> field of the <code>EPIHB8CFG</code> register.</p> <p>1 Different Baud Rates<br/>CS0n uses the baud rate for the external bus that is defined by the <code>COUNT0</code> field in the <code>EPIBAUD</code> register. CS1n uses the baud rate defined by the <code>COUNT1</code> field in the <code>EPIBAUD</code> register.<br/>CS2n uses the baud rate for the external bus that is defined by the <code>COUNT0</code> field in the <code>EPIBAUD2</code> register. CS3n uses the baud rate defined by the <code>COUNT1</code> field in the <code>EPIBAUD2</code> register.<br/>In addition, the sub-modes for each chip select are individually programmed in their respective <code>EPIHB8CFGn</code> registers.</p> |

| Bit/Field | Name     | Type | Reset | Description  |
|-----------|----------|------|-------|--|
| 25:24     | CSCFG    | RW   | 0x0   | <p>Chip Select Configuration</p> <p>This field controls the chip select options, including an ALE format, a single chip select, two chip selects, and an ALE combined with two chip selects. These bits are also used in combination with the CSCFGEXT bit for further configurations, including quad- chip select.</p> <p>Value Description</p> <p>0x0 ALE Configuration<br/>EPIOS30 is used as an address latch (ALE). The ALE signal is generally used when the address and data are muxed (HB8MODE field in the EPIHB8CFG register is 0x0). The ALE signal is used by an external latch to hold the address through the bus cycle.</p> <p>0x1 CSn Configuration<br/>EPIOS30 is used as a Chip Select (CSn). When using this mode, the address and data are generally not muxed (HB8MODE field in the EPIHB8CFG register is 0x1). However, if address and data muxing is needed, the WR signal (EPIOS29) and the RD signal (EPIOS28) can be used to latch the address when CSn is low.</p> <p>0x2 Dual CSn Configuration<br/>EPIOS30 is used as CS0n and EPIOS27 is used as CS1n. Whether CS0n or CS1n is asserted is determined by two methods. If only external RAM or external PER is enabled in the address map, the most significant address bit for a respective external address map controls CS0n or CS1n. If both external RAM and external PER is enabled, CS0n is mapped to PER and CS1n is mapped to RAM. This configuration can be used for a RAM bank split between 2 devices as well as when using both an external RAM and an external peripheral.</p> <p>0x3 ALE with Dual CSn Configuration<br/>EPIOS30 is used as address latch (ALE), EPIOS27 is used as CS1n, and EPIOS26 is used as CS0n. Whether CS0n or CS1n is asserted is determined by the most significant address bit for a respective external address map.</p> |
| 23:22     | reserved | RO   | 0x0   | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.  |

Sub-mode use is determined by the externally connected peripheral or memory. See Table 11-8 on page 823 for information on how this bit field affects the operation of the EPI signals.</p> <p><b>Note:</b> The CSBAUD bit must be set to enable this CS1n MODE field. If CSBAUD is clear, all chip-selects use the MODE configuration defined in the <b>EPIHB8CFG</b> register.</p> <p>Value Description</p> <p>0x0 ADMUX – AD[7:0]<br/>Data and Address are muxed.</p> <p>0x1 ADNONMUX – D[7:0]<br/>Data and address are separate.</p> <p>0x2-0x3 reserved</p>   |

## Register 9: EPI Host-Bus 16 Configuration 2 (EPIHB16CFG2), offset 0x014

**Important:** The `MODE` field in the `EPICFG` register determines which configuration register is accessed for offsets 0x010 and 0x014.

To access `EPIHB16CFG2`, the `MODE` field must be 0x3.

This register is used to configure operation while in Host-Bus 16 mode. Note that this register is reset when the `MODE` field in the `EPICFG` register is changed. If another mode is selected and the Host-Bus 16 mode is selected again, the values must be reinitialized.

### Register 10: EPI Address Map (EPIADDRMAP), offset 0x01C

This register enables address mapping. The EPI controller can directly address memory and peripherals. In addition, the EPI controller supports address mapping to allow indirect accesses in the External RAM and External Peripheral areas.

If the external device is a peripheral, including a FIFO or a directly addressable device, the `EPSZ` and `EPADR` bit fields should be configured for the address space. If the external device is SDRAM, SRAM, or NOR Flash memory, the `ERADR` and `ERSZ` bit fields should be configured for the address space.

If one of the dual chip select modes is selected (`CSCFGEXT` is 0x0 and `CSCFG` is 0x2 or 0x3 in the **EPIHBnCFG2** register), both chip selects can share the peripheral or the memory space, or one chip select can use the peripheral space and the other can use the memory space. In the **EPIADDRMAP** register, if the `EPADR` field is not 0x0, the `ECADR` field is 0x0, and the `ERADR` field is 0x0, then the address specified by `EPADR` is used for both chip selects, with `CS0n` being asserted when the MSB of the address range is 0 and `CS1n` being asserted when the MSB of the address range is 1. If the `ERADR` field is not 0x0, the `ECADR` field is 0x0, and the `EPADR` field is 0x0, then the address specified by `ERADR` is used for both chip selects, with the MSB performing the same delineation. If both the `EPADR` and the `ERADR` are not 0x0 and the `ECADR` field is 0x0, then `CS0n` is asserted for either address range defined by `EPADR` and `CS1n` is asserted for either address range defined by `ERADR`. The two chip selects can also be shared between the code space and memory or peripheral space. If the `ECADR` field is 0x1, `ERADR` field is 0x0, and the `EPADR` field is not 0x0, then `CS0n` is asserted for the address range defined by `ECADR` and `CS1n` is asserted for either address range defined by `EPADR`. If the `ECADR` field is 0x1, `EPADR` field is 0x0, and the `ERADR` field is not 0x0, then `CS0n` is asserted for the address range defined by `ECADR` and `CS1n` is asserted for either address range defined by `ERADR`.

If one of the Quad-Chip-Select modes is selected (`CSCFGEXT` is 0x1 and `CSCFG` is 0x2 or 0x3 in the **EPIHBnCFG2** register), both the peripheral and the memory space must be enabled. In the **EPIADDRMAP** register, the `EPADR` field is 0x3, the `ERADR` field is 0x3, and the `ECADR` field is 0x0. In this case, `CS0n` maps to 0x6000.0000; `CS1n` maps to 0x8000.0000; `CS2n` maps to 0xA000.0000; and `CS3n` maps to 0xC000.0000. The `MODE` field of the **EPIHBnCFGn** registers configures the interface for the individual chip selects, which support `ADMUX` or `ADNOMUX`. If the `CSBAUD` bit is clear, all chip selects use the mode configured in the `MODE` bit field of the **EPIHBnCFG** register. Table 11-5 on page 820 gives a detailed explanation of chip select address range mappings based on which combinations of peripheral and memory space are enabled.

**Register 11: EPI Read Size 0 (EPIRSIZE0), offset 0x020****Register 12: EPI Read Size 1 (EPIRSIZE1), offset 0x030**

This register selects the size of transactions when performing non-blocking reads with the **EPIRPSTDn** registers. This size affects how the external address is incremented.

The **SIZE** field must match the external data width as configured in the **EPIHBnCFG** or **EPIGPCFG** register.

SDRAM mode uses a 16-bit data interface. If **SIZE** is 0x1, data is returned on the least significant bits (D[7:0]), and the remaining bits D[31:8] are all zeros, therefore the data on bits D[15:8] is lost. If **SIZE** is 0x2, data is returned on the least significant bits (D[15:0]), and the remaining bits D[31:16] are all zeros.

Note that changing this register while a read is active has an unpredictable effect.

**EPI Read Size n (EPIRSIZEn)**

**Register 13: EPI Read Address 0 (EPIRADDR0), offset 0x024**

**Register 14: EPI Read Address 1 (EPIRADDR1), offset 0x034**

This register holds the current address value. When performing non-blocking reads via the **EPIRSTDn** registers, this register's value forms the address (when used by the mode). That is, when an **EPIRSTDn** register is written with a non-0 value, this register is used as the first address. After each read, it is incremented by the size specified by the corresponding **EPIRSIZEn** register. Thus at the end of a read, this register contains the next address for the next read. For example, if the last read was 0x20, and the size is word, then the register contains 0x24. When a non-blocking read is cancelled, this register contains the next address that would have been read had it not been cancelled. For example, if reading by bytes and 0x103 had been read but not 0x104, this register contains 0x104. In this manner, the system can determine the number of values in the NBRFIFO to drain.

Note that changing this register while a read is active has an unpredictable effect due to race condition.

**Register 15: EPI Non-Blocking Read Data 0 (EPIRPSTD0), offset 0x028****Register 16: EPI Non-Blocking Read Data 1 (EPIRPSTD1), offset 0x038**

This register sets up a non-blocking read via the external interface. A non-blocking read is started by writing to this register with the count (other than 0). Clearing this register terminates an active non-blocking read as well as cancelling any that are pending. This register should always be cleared before writing a value other than 0; failure to do so can cause improper operation. Note that both NBR channels can be enabled at the same time, but NBR channel 0 has the highest priority and channel 1 does not start until channel 0 is finished.

The first address is based on the corresponding **EPIADDRn** register. The address register is incremented by the size specified by the **EPIRSIZEn** register after each read. If the size is less than a word, only the least significant bits of data are filled into the NBRFIFO; the most significant bits are cleared.

Note that all three registers may be written using one STM instruction, such as with a structure copy in C/C++.

The data may be read from the **EPIREADFIFO** register after the read cycle is completed. The interrupt mechanism is normally used to trigger the FIFO reads via ISR or  $\mu$ DMA.

If the countdown has not reached 0 and the NBRFIFO is full, the external interface waits until a NBRFIFO entry becomes available to continue.

Note: if a blocking read or write is performed through the address mapped area (at 0x6000.0000 through 0xDFFF.FFFF), any current non-blocking read is paused (at the next safe boundary), and the blocking request is inserted. After completion of any blocking reads or writes, the non-blocking reads continue from where they were paused.

The other way to read data is via the address mapped locations (see the **EPIADDRMAP** register), but this method is blocking (core or  $\mu$ DMA waits until result is returned).

To cancel a non-blocking read, clear this register. To make sure that all values read are drained from the NBRFIFO, the **EPISTAT** register must be consulted to be certain that bits **NBRBUSY** and **ACTIVE** are cleared. One of these registers should not be cleared until either the other **EPIRPSTDn** register becomes active or the external interface is not busy. At that point, the corresponding **EPIADDRn** register indicates how many values were read.

## Register 17: EPI Status (EPISTAT), offset 0x060

This register indicates which non-blocking read register is currently active; it also indicates whether the external interface is busy performing a write or non-blocking read (it cannot be performing a blocking read, as the bus would be blocked and as a result, this register could not be accessed).

This register is useful for determining which non-blocking read register is active when both are loaded with values and when implementing sequencing or sharing.

This register is also useful when canceling non-blocking reads, as it shows how many values were read by the canceled side.

### Register 18: EPI Read FIFO Count (EPIRFIFOCNT), offset 0x06C

This register returns the number of values in the NBRFIFO (the data in the NBRFIFO can be read via the **EPIREADFIFO** register). A race is possible, but that only means that more values may come in after this register has been read.

#### EPI Read FIFO Count (EPIRFIFOCNT)

**Register 19: EPI Read FIFO (EPIREADFIFO0), offset 0x070**

**Register 20: EPI Read FIFO Alias 1 (EPIREADFIFO1), offset 0x074**

**Register 21: EPI Read FIFO Alias 2 (EPIREADFIFO2), offset 0x078**

**Register 22: EPI Read FIFO Alias 3 (EPIREADFIFO3), offset 0x07C**

**Register 23: EPI Read FIFO Alias 4 (EPIREADFIFO4), offset 0x080**

**Register 24: EPI Read FIFO Alias 5 (EPIREADFIFO5), offset 0x084**

**Register 25: EPI Read FIFO Alias 6 (EPIREADFIFO6), offset 0x088**

**Register 26: EPI Read FIFO Alias 7 (EPIREADFIFO7), offset 0x08C**

**Important:** This register is read-sensitive. See the register description for details.

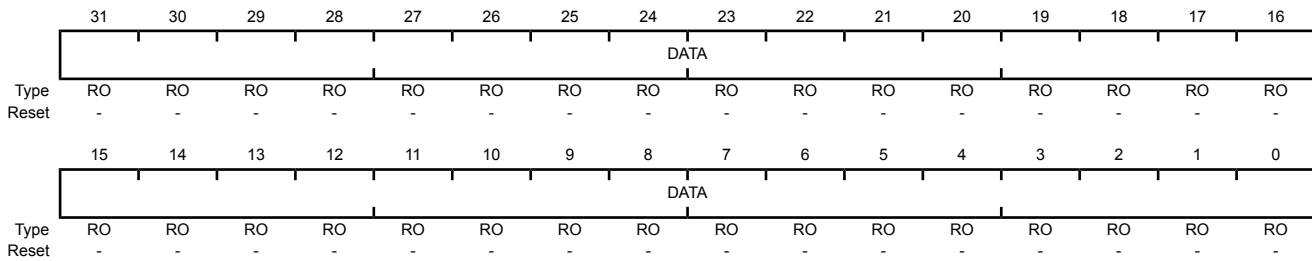

This register returns the contents of the NBRFIFO or 0 if the NBRFIFO is empty. Each read returns the data that is at the top of the NBRFIFO, and then empties that value from the NBRFIFO. The alias registers can be used with the LDmia instruction for more efficient operation (for up to 8 registers). See *Cortex™-M3/M4 Instruction Set Technical User's Manual (literature number SPMU159)* for more information on the LDmia instruction.

**Register 27: EPI FIFO Level Selects (EPIFIFOLVL), offset 0x200**

This register allows selection of the FIFO levels which trigger an interrupt to the interrupt controller or, more efficiently, a DMA request to the  $\mu$ DMA. The NBRFIFO select triggers on fullness such that it triggers on match or above (more full) in order for the processor or the  $\mu$ DMA to extract the read data. The WFIFO triggers on emptiness such that it triggers on match or below (less entries) in order for the processor or the  $\mu$ DMA to insert more write data.

It should be noted that the FIFO triggers are not identical to other such FIFOs in TM4C129CNCZAD peripherals. In particular, empty and full triggers are provided to avoid wait states when using blocking operations.

The settings in this register are only meaningful if the  $\mu$ DMA is active or the interrupt is enabled.

Additionally, this register allows protection against writes stalling and notification of performing blocking reads which stall for extra time due to preceding writes. The two functions behave in a non-orthogonal way because read and write are not orthogonal.

The write error bit configures the system such that an attempted write to an already full WFIFO abandons the write and signals an error interrupt to prevent accidental latencies due to stalling writes.

The read error bit configures the system such that after a read has been stalled due to any preceding writes in the WFIFO, the error interrupt is generated. Note that the excess stall is not prevented, but an interrupt is generated after the fact to notify that it has happened.

**Register 28: EPI Write FIFO Count (EPIWFIFOCNT), offset 0x204**

This register contains the number of slots currently available in the WFIFO. This register may be used for polled writes to avoid stalling and for blocking reads to avoid excess stalling (due to undrained writes). An example use for writes may be:

```
for (idx = 0; idx < cnt; idx++) {
while (EPIWFIFOCNT == 0) ;
*ext_ram = *mydata++;
}
```

The above code ensures that writes to the address mapped location do not occur unless the WFIFO has room. Although polling makes the code wait (spinning in the loop), it does not prevent interrupts being serviced due to bus stalling.

## Register 30: EPI Interrupt Mask (EPIIM), offset 0x210

This register is the interrupt mask set or clear register. For each interrupt source (read, write, and error), a mask value of 1 allows the interrupt source to trigger an interrupt to the interrupt controller; a mask value of 0 prevents the interrupt source from triggering an interrupt.

**Register 31: EPI Raw Interrupt Status (EPIRIS), offset 0x214**

This register is the raw interrupt status register. On a read, it gives the current state of each interrupt source. A write has no effect.

Note that raw status for read and write is set or cleared based on FIFO fullness as controlled by **EPIFIFOLVL**.

Raw status for error is held until the error is cleared by writing to the **EPIEISC** register.

## Register 32: EPI Masked Interrupt Status (EPIMIS), offset 0x218

This register is the masked interrupt status register. On read, it gives the current state of each interrupt source (read, write, and error) after being masked via the **EPIIM** register. A write has no effect.

The values returned are the ANDing of the **EPIIM** and **EPIRIS** registers. If a bit is set in this register, the interrupt is sent to the interrupt controller.

**Register 33: EPI Error and Interrupt Status and Clear (EPIEISC), offset 0x21C**

This register is used to clear a pending error interrupt. Clearing any defined bit in the **EPIEISC** has no effect; setting a bit clears the error source and the raw error returns to 0. When any of bits[2:0] of this register are read as set, it indicates that the **ERRRIS** bit in the **EPIRIS** register is set and an EPI controller error is sent to the interrupt controller if the **ERIM** bit in the **EPIIM** register is set. If any of bits [2:0] are written as 1, the register bit being written to, as well as the **ERRRIS** bit in the **EPIRIS** register and the **ERIM** bit in the **EPIIM** register are cleared. If the **DMAWRIC** or **DMARDIC** bit in this register is set, then the corresponding bit in the **EPIRIS** and **EPIMIS** register is cleared. Note that writing to this register and reading back immediately (pipelined by the processor) returns the old register contents. One cycle is needed between write and read.

**EPI Error and Interrupt Status and Clear (EPIEISC)**

**Register 43: EPI Host-Bus 16 Timing Extension (EPIHB16TIME3), offset 0x318**

**Important:** The `MODE` field in the `EPICFG` register determines which configuration is enabled.

For `EPIHB16TIME3` to be valid, the `MODE` field must be 0x3.

**Register 44: EPI Host-Bus 8 Timing Extension (EPIHB8TIME4), offset 0x31C**

**Important:** The `MODE` field in the `EPICFG` register determines which configuration is enabled.

For `EPIHB8TIME4` to be valid, the `MODE` field must be 0x2.

**Register 46: EPI Host-Bus PSRAM (EPIHBPSRAM), offset 0x360**

This register holds the PSRAM configuration register value. When the `WRCRE` bit in the `EPIHB16CFGn` register is set, all 21 bits of the `EPIHBPSRAM` register's `CR` value are written to the PSRAM's configuration register. When the `RDCRE` bit is set in the `EPIHB16CFGn` register, a read of the PSRAM's configuration register takes place and the value is written to bits[15:0] of the `EPIHBPSRAM`. Bits[20:16] will not contain any valid data.

## 12 Cyclical Redundancy Check (CRC)

The Cyclical Redundancy Check (CRC) computation module can be used for message transfer and safety system checks, as well as in conjunction with the AES and DES modules. The following features are supported:

- Support four major CRC forms:
  - CRC16-CCITT as used by CCITT/ITU X.25
  - CRC16-IBM as used by USB and ANSI
  - CRC32-IEEE as used by IEEE802.3 and MPEG2
  - CRC32C as used by G.Hn
- Allows word and byte feed
- Supports auto-initialization and manual initialization
- Supports MSb and LSb
- Supports CCITT post-processing
- Can be fed by  $\mu$ DMA, Flash memory and code

### 12.1 Functional Description

The following sections describe the features of CRC.

#### 12.1.1 CRC Support

The purpose of the CRC engine is to accelerate CRC and TCP checksum operation. The result of the CRC operation is a 32- and 16-bit signature which can be used to check the sanity of data. The required mode of operation is selected through the `TYPE` bit in the **CRC Control (CRCCTRL)** register, offset 0x400. A  $\mu$ DMA software channel can be used to burst data into the CRC module. CRCs are computed combinatorially in one clock.

The CRC module contains all of the control registers to which the input context interfaces. Because CRC calculations are a single cycle, as soon as data is written to **CRC Data Input (CRCDIN)** register, the result of CRC/CSUM is updated in the **CRC SEED/Context (CRCSEED)** register, offset 0x410. The input data is computed by the selected CRC polynomial or CSUM.

##### 12.1.1.1 CRC Checksum engine

Software can offload the CRC and checksum task to the CRC checksum engine accelerator. The accelerator has registers that need to be programmed to initiate processing. These registers should be fed with data in order to calculate CRC/CSUM. Software should configure the  $\mu$ DMA channel for data movement through the **DMA Channel Map Select n (DMACHMAPn)** register in the  $\mu$ DMA module. Further  $\mu$ DMA configuration guidelines are available in the “Micro Direct Memory Access ( $\mu$ DMA)” on page 667.

The starting seed for the CRC and checksum operation is programmed in the **CRC SEED/Context (CRCSEED)** register at offset 0x410. Depending on the encoding of the `INIT` field in the **CRCCTRL** register, the value of the `SEED` field can be initialized to any one of the following:

- A unique context value written to the **CRCSEED** register (`INIT=0x0`)
- All 0s (`INIT=0x2`)
- All 1s (`INIT=0x3`)

Once the operation is done, software should read the result from the **CRC Post Processing Result (CRCRSLTPP)** register, offset 0x418, and a software channel  $\mu$ DMA interrupt should be used to identify completion.

### 12.1.1.2 Data Size

The CRC module supports data being fed 32-bit words and 8 bits at a time and can dynamically switch back and forth. The data size is configured by programming the `SIZE` bit in the **CRCCTRL** register, offset 0x400.

Because CRC is a division on a long stream of bits, the application must take into consideration the bit order. When processing message data that is read out by words, bit order is not an issue. For example, if the data value in the message is 0x12345678, the most significant eight byte is 0x12 (00010010 in binary). If the data is processed as bytes, 0x12, 0x34, 0x56, and 0x78 are copied into memory in that order and the word is stored as 0x78563412, where 0x12 is written as byte 0, 0x34 is written as byte 1, and so on.

### 12.1.1.3 Endian Configuration

The following endian configuration is provided by the `ENDIAN` field in the **CRCCTRL** register:

- Swap byte in half-word
- Swap half word

Input data width is four bytes, hence the configuration only affects the four-byte word. The `ENDIAN` bit field supports the following configurations, assuming the input word is {B3, B2, B1, B0}

**Table 12-1. Endian Configuration**

| ENDIAN Encoding | Definition   | Configuration    |
|-----------------|--|------------------|
| 0x0             | Configuration unchanged.                                       | {B3, B2, B1, B0} |
| 0x1             | Bytes are swapped in half-words but half-words are not swapped | {B2, B3, B0, B1} |
| 0x2             | Half-words are swapped but bytes are not swapped in half-word. | {B1, B0, B3, B2} |
| 0x3             | Bytes are swapped in half-words and half-words are swapped.    | {B0, B1, B2, B3} |

Bit reversal is supported by the `BR` bit in the **CRCCTRL** register. The bit reversal operation works in tandem with endian control. For example, the above table with the `BR` option set would look like this:

**Table 12-2. Endian Configuration with Bit Reversal**

| ENDIAN Encoding | Initial Endian Configuration  | Configuration with Bit Reversal (BR = 1) |
|-----------------|---|--|
| 0x0             | Configuration unchanged.<br>{B3[31:24], B2[23:16], B1[15:8], B0[7:0]} | B3[24:31], B2[16:23], B1[8:15], B0[0:7]  |

Table 12-2. Endian Configuration with Bit Reversal (*continued*)

| ENDIAN Encoding | Initial Endian Configuration  | Configuration with Bit Reversal (BR = 1) |
|-----------------|---|--|
| 0x1             | Bytes are swapped in half-words but half-words are not swapped<br>{B2[23:16], B3[31:24], B0[7:0], B1[15:8]} | B2[16:23],B3[24:31],B0[0:7],B1[8:15]     |
| 0x2             | Half-words are swapped but bytes are not swapped in half-word.<br>{B1[15:8], B0[7:0], B3[31:24], B2[23:16]} | B1[8:15],B0[0:7],B3[24:31],B2[16:23]     |
| 0x3             | Bytes are swapped in half-words and half-words are swapped<br>{B0[7:0], B1[15:8], B2[23:16], B3[31:24]}     | B0[0:7],B1[8:15],B2[16:23],B3[24:31]     |

## 12.2 Initialization and Configuration

The following describes the initialization and configuration procedures of the CRC module.

### 12.2.1 CRC Initialization and Configuration

The CRC engine works in push through mode, which means it works on streaming data. This section describes the steps for initializing the CRC module:

1. Enable the CRC by setting the `R0` bit in the CRC and Cryptographic Modules (RCGCCM) register, System Control offset 0x674.
2. Configure the desired CRC data size, bit order, endian configuration and CRC type by programming the **CRC Control (CRCCTRL)** register, offset 0x400.
3. If the CRC value has not been initialized to all 0s or all 1s using the `INIT` field in the **CRCCTRL** register, program the initial value in the **CRC SEED/Context (CRCSEED)** register, offset 0x410.
4. Repeatedly write the `DATAIN` field in the **CRC Data Input (CRCDIN)** register, offset 0x414. If the `SIZE` bit in the **CRCCTRL** register is set to select byte, the CRC engine operates in byte mode and only the least significant byte is used for CRC calculation.
5. When CRC is finished, read the **CRCSEED** register for the final result. If using post-processing, the raw CRC result is stored in the **CRCSEED** register and the final, post-processed result can be read from the **CRC Post-Processing Result (CRCRSLTPP)** register, offset 0x418. Post-processing options are selectable through the `OBR` and `OLNV` bits of the **CRCCTRL** register.

Alternatively a software  $\mu$ DMA channel can be configured to copy data from the source into the **CRCDIN** register. When configuring the  $\mu$ DMA, the destination should be configured to not increment. For more information on how to configure the  $\mu$ DMA, refer to “Micro Direct Memory Access ( $\mu$ DMA)” on page 667.

#### 12.2.1.1 Data Endian Convention for the CRC Engine

If the input stream is expressed as a byte stream, `Din`, where `Din` = {D0, D1, D2, D3, D4, D5, D6, D7, D8, D9, D11, D12, D13, D14, D15, D16.....}, then data should be fed to the CRC engine as follows:

- If operating in Byte mode, the **CRCDIN** register should be written in the following order:
  1. {00, 00, 00, D0}

2. {00, 00, 00, D1}
3. {00, 00, 00, D2}
4. {00, 00, 00, D3}
5. {00, 00, 00, D4}
6. {00, 00, 00, D5}
7. {00, 00, 00, D6}
8. ....
9. ....

- If operating in word mode, the **CRC DIN** register should be written in the following order:

1. {D3, D2, D1, D0}
2. {D7, D6, D5, D4}
3. {D11, D10, D9, D8}
4. ....
5. ....

## 12.3 Register Map

Table 12-3 on page 941 lists the CRC Module registers. The offset listed is a hexadecimal increment to the register's address, relative to the base address 0x4403.0000.

**Table 12-3. CCM Register Map**

| Offset | Name      | Type | Reset       | Description                | See page |
|--------|-----------|------|-------------|----------------------------|----------|
| 0x400  | CRCCTRL   | RW   | 0x0000.0000 | CRC Control                | 942      |
| 0x410  | CRCSEED   | RW   | 0x0000.0000 | CRC SEED/Context           | 944      |
| 0x414  | CRC DIN   | RW   | 0x0000.0000 | CRC Data Input             | 945      |
| 0x418  | CRCRSLTPP | RO   | 0x0000.0000 | CRC Post Processing Result | 946      |

## 12.4 CRC Module Register Descriptions

This section lists and describes the CRC registers, in numerical order by address offset.

**Note:** The CRC module can only be accessed through privileged mode. If the  $\mu$ DMA is used for CRC transfers, then the  $\mu$ DMA's **DMA Channel Control (DMACHCTL)** register also needs to be programmed to allow for privileged accesses.

### Register 1: CRC Control (CRCCTRL), offset 0x400

The **CRC Control (CRCCTRL)** register is used to configure control of the CRC.

#### CRC Control (CRCCTRL)

Base 0x4403.0000  
 Offset 0x400  
 Type RW, reset 0x0000.0000

| Bit/Field | Name     | Type | Reset  | Description   |

### Register 2: CRC SEED/Context (CRCSEED), offset 0x410

The **CRC SEED/Context (CRCSEED)** register is initially written with one of the following three values depending on the encoding of the **INIT** field in the **CRCCTRL** register:

- The context value written to the **CRCSEED** register. This encoding is for **SEED** values from a previous CRC calculation or a specific protocol. (**INIT**=0x0)
- 0x0000.0000 (**INIT**=0x2)
- 0x1111.1111 (**INIT**=0x3)

#### CRC SEED/Context (CRCSEED)

Base 0x4403.0000  
 Offset 0x410  
 Type RW, reset 0x0000.0000

## 13 Advance Encryption Standard Accelerator (AES)

This section describes the Advanced Encryption Standard (AES) cryptographic hardware-accelerated module.

### 13.1 AES Overview

This section introduces the AES and describes the AES main functions and connections in the device.

The advanced encryption standard (AES) security modules provide hardware-accelerated data encryption and decryption operations based on a binary key. The AES is a symmetric cipher module that supports a 128-bit, 192-bit, or 256-bit key in hardware for both encryption and decryption. The AES module is based on a symmetric algorithm, meaning that the encryption and decryption keys are identical. To encrypt data means to convert it from plain text to an unintelligible form called cipher text. Decrypting cipher text converts previously encrypted data back to its original plain text form.

The main features of the AES accelerator are:

- Support for basic AES encrypt and decrypt operations:
  - Galois/Counter Mode (GCM), with basic GHASH operation
  - Counter Mode with CBC-MAC (CCM)
  - XTS Mode
- Availability of the following feedback operating modes:
  - Electronic Code Book Mode (ECB)
  - Cipher Block Chaining Mode (CBC)
  - Counter Mode (CTR)
  - Cipher Feedback Mode (CFB), 128-bit
  - F8 Mode
- Key sizes 128-, 192- and 256-bits
- Support for CBC\_MAC and Fedora 9 (F9) authentication modes
- Basic GHASH operation (when selecting no encryption)
- Key scheduling in hardware
- Support for  $\mu$ DMA transfers
- Fully synchronous design

### 13.2 AES Functional Description

The following sections describe the features of the AES Module.

### 13.2.1 AES Block Diagram

Figure 13-1 on page 948 shows the AES block diagram. A single-core/dual-interface architecture is used.

**Figure 13-1. AES Block Diagram**

AES is an efficient implementation of the Rijndael cipher (the AES algorithm) and a 128-bit polynomial multiplication (referred to here as GHASH, as per the AES-GCM specification). Rijndael is a block cipher in which each data block is 128 bits. The polynomial multiplication multiplies two 128-bit vectors using the smallest 128-bit irreducible polynomial, represented by the following 128-bit string:  $\{0^{120}\}||10000111$ . The two implementations are combined into the AES wide-bus engine.

Depending on the availability of context and data, the AES wide-bus engine is automatically triggered to process the data. The AES wide-bus engine is directly connected to the context and data registers so that it can immediately start processing when all data is available. The AES wide-bus engine also interfaces to the I/O Control FSM/ $\mu$ DMA Request Interface.

AES comprises the following major functional blocks:

- Global control FSM and  $\mu$ DMA interface
- Register interface module
- The AES wide-bus engine

The AES wide-bus engine, which is the major top-level component, comprises the following functional blocks:

- Mode control FSM: Manages the data flow to and from the AES wide-bus engine and starts each encryption/decryption operation.

- Feedback modes: The logic that implements the various feedback modes supported by AES.
- GHASH core: The polynomial multiplication algorithm used for AES-GCM
- AES key scheduler: Generates AES encryption and decryption (round) keys
- AES encryption core: The AES encryption algorithm
- AES decryption core: The AES decryption algorithm
- Substitution-boxes (S-Boxes): Contain AES S-Box GF(2<sup>8</sup>) implementations

AES encryption requires a specific number of rounds, depending on the key length. The supported key lengths are 128-, 192-, and 256-bit, which require 10, 12, and 14 rounds, respectively, or 32, 38, and 44 clock cycles, respectively, because {number of clock cycles} = 2 + 3 x {number of rounds}.

The larger key lengths provide greater encryption strength at the expense of additional rounds and therefore reduced throughput. The overall throughput of the AES executing polynomial multiplication is adjusted based on the overall cryptographic performance. The AES module contains one Electronic Codebook (ECB) core and a dedicated 32-cycle polynomial multiplication module for performing GHASH operations. Polynomial multiplication operates in parallel with the AES core, if data is available for both modules.

Depending on the key size (128/192/256 bits), this core requires 32, 38, or 44 clock cycles to process one 128-bit data block. While one data block processes, the next block can be preloaded immediately. When a block is preloaded, the previous block must finish before additional data can be loaded. Therefore, once the pipeline is full, sequential data blocks can be passed every 32, 38, or 44 clock cycles.

### 13.2.1.1 Interfaces

The interface signals to the AES module can be grouped into the following four categories:

- Clock and reset signals
- Register interface
- $\mu$ DMA/INT interface, used to request new context and packet data or to indicate available result data (encrypted/decrypted data or authentication result)

### 13.2.1.2 Register Interface

The register interface block performs all address decoding and control. However, not all registers are located in this block. The context and data input registers are in the AES wide-bus engine. The data output registers are available in this block.

### 13.2.1.3 AES Wide-Bus Engine

The AES wide-bus engine performs the cryptographic operations. The composition of the AES core is:

- The main data path operates on the input block, performing the required substitution, shift, and mix operations.
- The key scheduler generates the round keys. A new subkey is generated and XORed with the data each round.

### **AES Key Scheduler**

The AES key scheduler generates the round keys. During each round, a new subkey is generated from the input key to be XORed with the data. Round keys are generated on-the-fly and parallel to data processing to minimize register requirements.

For encryption operations, the key sequencer transfers the initial key data to the AES core. For decryption operations, the key scheduler must provide the final subkey to the AES core so it can generate the subkeys in reverse order.

### **AES Encryption Core**

The AES encryption core implements the Rijndael algorithm as specified in [ FIPS-197]. This core operates on the input block and performs the required substitution, shift, and mix operations. For each round, the encryption core receives the proper round key from the AES key scheduler. A fundamental component of the AES algorithm is the S-Box. The S-Box provides a unique 8-bit output for each 8-bit input. This implementation of the AES encryption core has a 64-bit data path.

### **AES Decryption Core**

The architecture of the AES decryption core is generally the same as the architecture of the encryption core. One difference is that the generation of round keys for decryption requires an initial conversion of the input key (always supplied by the host in the form of an encryption key) to the corresponding decryption key. This conversion is done by performing a dummy encryption operation and storing the final round key as a decryption key. The key scheduler is then reversed to generate the round keys for the decryption operation. Consequently, for each sequence of decryption operations under the same key, a single throughput reduction equal to the time to encrypt a single block occurs. Once a decryption key is generated, subsequent decryption operations with the same key use this generated decryption key directly.

### **AES Feedback Mode Block**

The AES feedback mode block buffers the feedback parameters and controls the various feedback modes. For more information about the ECB, CBC, CTR, and CFB modes of operation, see the [NIST-SP800-38A](#) specification.

CTR implements the standard incrementing function, as described in the NIST-SP800-38A specification, with  $m$  set to 16 or a multiple of 32.

AES-XTS mode requires a polynomial multiplication for initialization vector (IV) generation of the AES operation. This multiplication can be simplified when the first result is available due to the definition and use of the block number within a unit. The input for the polynomial multiplication is not directly  $j$ , but  $\alpha^j$ , where  $\alpha = x^2$  in the  $GF(2^{128})$  domain.

In addition, f8 encryption/decryption mode and f9 and (X)CBC-MAC authentication modes are available.

### **GHASH Block**

The data sequencer manages the data flow to and from the AES core. For data input, the data sequencer monitors the input buffer until a 16-byte block is available. If the AES core is idle, the data sequencer writes this data block to the internal working registers of the AES core, thus clearing the buffer for the next block.

After completing an encryption or decryption operation, the data sequencer writes the AES output to the output buffer. If the output buffer is full at the time of completion, the AES core is held until the buffer clears. Although the data sequencer is designed to support uninterrupted packet encryption, the host must properly manage the input and output packet buffers to achieve optimal performance.

### 13.2.2 AES Algorithm

The AES algorithm generates block ciphers. The AES block size is 16 bytes. The AES key(s) can be coded on 128, 192, or 256 bits. The larger key sizes provide a higher level of security, but at the cost of a moderate decrease in throughput.

For the AES algorithm:

- The length of the input and output blocks is 128 bits, which is represented by  $N_b = 4$ , which reflects the number of 32-bit words.
- The length of the cipher key (K) is 128, 192, or 256 bits. The key length is represented by  $N_k = 4, 6, \text{ or } 8$ , which reflects the number of 32-bit words in the cipher key.
- The number of rounds to be performed during the execution of the algorithm is dependent on the key size. The number of rounds is represented by  $N_r$ , where  $N_r = 10$  when  $N_k = 4$  (128-bit key);  $N_r = 12$  when  $N_k = 6$  (192-bit key); and  $N_r = 14$  when  $N_k = 8$  (256-bit key).

Table 13-1 on page 951 lists the combinations of keys, blocks, and rounds.

**Table 13-1. Key-Block-Round Combinations**

| Key      | Key Length (Nk) | Block Size (Nb) | Number of Rounds (Nr) |
|----------|-----------------|-----------------|-----------------------|
| 128 bits | 4               | 4               | 10                    |
| 192 bits | 6               | 4               | 12                    |
| 256 bits | 8               | 4               | 14                    |

The AES algorithm for cipher and inverse cipher uses a round function composed of four different byte-oriented transformations:

- Byte substitution using a substitution table (S-Box)
 

This transformation is a non-linear byte substitution that operates independently on each byte of the state (the state is an intermediate processed block of 128 bits inside the AES; the state is arranged as an array of  $[4 \times N_k]$  bytes) using an S-Box. This S-Box transformation is reversible.
- Shifting rows of the state array by different offsets
 

In this transformation, the bytes in the last three rows of the state are cyclically shifted over different numbers of bytes (offsets). The first row ( $r = 0$ ) is not shifted.
- Mixing the data within each column of the state array
 

This transformation operates on the state column-by-column, treating each column as a four-term polynomial. The columns are considered polynomials over  $GF(2^8)$  and multiplied modulo  $x^4 + 1$  with a fixed polynomial  $a(x)$ .
- Adding a round key to the state
 

In this transformation, a round key is added to the state by a simple bitwise XOR operation. Each round key consists of  $N_b$  words from the key schedule.

The AES algorithm takes the cipher key (K) and performs a key expansion routine to generate a key schedule. The key expansion generates a total of  $N_b \times (N_r + 1)$  words: The algorithm requires an initial set of  $N_b$  words, and each of the  $N_r$  rounds requires  $N_b$  words of key data. The resulting key schedule consists of a linear array of 4-byte words, denoted  $[w_i]$ , with  $i$  in the range  $0 \leq i < N_b \times (N_r + 1)$ .

## 13.2.3 AES Operating Modes

### 13.2.3.1 Supported Modes of Operation

#### **ECB Feedback Mode**

Figure 13-2 on page 952 shows the basic ECB feedback mode of operation, where the input data is passed directly to the basic cryptographic core and the output is passed directly to the output buffer.

For decryption, the cryptographic core operates in reverse: the decryption data path is used for data processing, whereas encryption uses the encryption data path.

**Figure 13-2. AES - ECB Feedback Mode**

#### **CBC Feedback Mode**

Figure 13-3 on page 953 shows the CBC feedback mode of operation, where the input data is XORed with the IV before it is passed to the basic cryptographic core. The output of the cryptographic core passes directly to the output buffer and becomes the next IV.

The operation is reversed for decryption, resulting in an XOR at the output of the cryptographic core. The input cipher text of the current operation is the IV for the next operation.

Figure 13-3. AES - CBC Feedback Mode

**CTR and ICM Feedback Modes**

Figure 13-4 on page 953 shows the counter feedback (CTR/ICM) mode of operation. This operation encrypts the IV. The output of the cryptographic core (encrypted IV) is XORed with the data, thus creating the output result.

The IV is built out of two components: a fixed part and a counter part. The counter part is incremented with each block. The counter width is selectable per context and can be 16, 32, 64, 96, or 128 bits wide. In this mode, encryption and decryption use the same operation.

Figure 13-4. AES Encryption With CTR/ICM Mode

**Note:** The value for n can be 1, 2, 3, or 4 for CTR mode and is ½ for ICM mode.

**CFB Mode**

Figure 13-5 on page 954 shows the full block (128 bits) CFB mode of operation for encryption and decryption. The input for the cryptographic core is the IV; the result is XORed with the data. The result is fed back through the IV register as the next input for the cryptographic core. The decryption operation is reversed, but the cryptographic core still performs encryption.

**Figure 13-5. AES - CFB Feedback Mode**

**F8 Mode**

Figure 13-6 on page 955 shows the F8 feedback mode of operation for encryption and decryption. The input to the cryptographic core is the result of the XOR operation of the previous cryptographic core output, a constant IV, and a block counter. The output of the cryptographic core is XORed with the input to create the result. In this mode, encryption and decryption use the same operations.

Figure 13-6. AES - F8 Mode

**XTS Operation**

Figure 13-7 on page 955 shows the XTS mode of operation for encryption and decryption. The input to the cryptographic core is XORed with the IV; the output of the cryptographic core is XORed with the same IV. For decryption, the cryptographic core operates in reverse, but the XOR operations are the same.

Figure 13-7. AES - XTS Operation

**Note:** The IV is created with an initial encryption, followed by an LFSR operation for each new block.

### F9 Operation

Figure 13-8 on page 956 shows the F9 authentication mode of operation, where the input to the cryptographic core is XORed with the IV, and the output is XORed with the previous result to create the next result. The cryptographic core output is fed back as IV for the next block. The result is the output of the last XOR operation of the cryptographic core output.

**Figure 13-8. AES - F9 Operation**

### CBC-MAC Operation

Figure 13-9 on page 957 shows the CBC-MAC authentication mode of operation, where the input to the cryptographic core is XORed with the IV. The cryptographic core output is then fed back as IV for the next block. The last data input block is XORed with an additional input value stored in the temporary buffer; this can be any precalculated value and is dependent on the alignment of the last input block. The result is the cryptographic core output of the last encryption operation.

**Figure 13-9. AES - CBC-MAC Authentication Mode****GCM Operation**

Figure 13-10 on page 958 shows one round of a GCM operation for encryption and decryption. A 32-bit counter is used as IV (as it is for CTR mode). The data is encrypted in the same way as in CTR mode, by XORing the cryptographic core output with the input. After the encryption/decryption, the ciphertext is XORed with the intermediate authentication result. The XORed result is used as input for the polynomial multiplication to create the next (intermediate) authentication result. For more information about the GCM protocol, see the section called “GCM Protocol Operation” on page 959.

Figure 13-10. AES - GCM Operation

**CCM Operation**

Figure 13-11 on page 959 shows one round of a CCM (counter with CBC-MAC) operation for encryption and decryption. A 32-bit counter is used as IV (as it is for CTR mode). The data is encrypted in the same way as in CTR mode, by XORing the cryptographic core output with the input. Immediately after the encryption operation, the plaintext is XORed with the intermediate authentication result. The XOR result is used as input for a second encryption operation to calculate the next (intermediate) authentication result.

Figure 13-11. AES - CCM Operation

### 13.2.3.2 Extended and Combined Modes of Operations

This section describes the protocols (or autonomous precalculations) supported by the AES wide-bus engine.

#### **GCM Protocol Operation**

A GCM protocol operation is a combined operation consisting of encryption/decryption and authentication. A part of the input data stream can be authenticated only, while normally most of the input data is encrypted/decrypted and authenticated. The authentication-only data must always be in front of the data requiring encryption. Within GCM, the authentication-only data is called the additional authentication data (AAD). The AAD is fetched independently of other data.

The intermediate (temporary) result data is used as input to the remaining authentication operation. Because the authentication operation does not require the cryptographic core but only the polynomial multiplication, encryption/decryption and authentication can be performed in parallel. After encryption of the last data block, additional polynomial multiplication and encryption are required to authenticate a 128-bit length vector and finally encrypt the authentication result.

#### **CCM Protocol Operation**

The CCM protocol operation is a combined operation consisting of encryption/decryption and authentication. The authentication and encryption/decryption operations use the cryptographic core; these are executed sequentially on the AES core. A part of the data stream can require authentication only. The authentication-only data must always be in front of the data requiring encryption.

Authentication starts with the encryption of a predefined block B0. This block consists of flags, nonce, and message length. The next blocks contain the authentication data length concatenated with the authentication-only data. After processing the authentication-only data, the encryption/decryption operations are performed, each followed by the related authentication of the plaintext data block (which equals the input in the case of encryption, and the output in the case of

decryption). The final authentication result must be encrypted using the output of the encryption of the IV block A0. This block contains the IV (consisting of flags and nonce) concatenated with the counter, which is zero for A0.

### 13.2.4 AES Software Reset

To perform a software reset of the AES module, write a 1 to the `SOFTRESET` bit in the **AES System Configuration (AES\_SYSCONFIG)** register. The `RESETDONE` bit in the **AES Secure System Status (AES\_SYSSTATUS)** register indicates that the software reset is complete when its value is 1. When the software reset completes, the `SOFTRESET` bit in the **AES\_SYSCONFIG** register is automatically reset. Software must ensure that the software reset completes before doing any operations.

The behavior of the software reset is the same as the hardware reset, except that the software reset bit resets this module without affecting the reset core domain of the entire device.

### 13.2.5 Power Management

To save power, the application can disable the clock to the AES module when not in use. The AES is clock gated by setting the `AESCFG` bit in the **Cryptographic Modules Clock Gating Request (CCMCGREQ)** register, CRC and Cryptographic Modules (CCM) offset 0x204. The AES in addition to the DES, SHA/MD5 and CRC can also be clock gated as a group by setting the `D0` bit in the **CRC and Cryptographic Modules (DCGCCM)** register, System Control Module offset 0x874.

### 13.2.6 Hardware Requests

The AES module can assert a  $\mu$ DMA request for context in, context out, input data, or output data read. The **AES uDMA Interrupt Mask (AES\_DMAIM)** register can be set to generate interrupts during the following events:

- Context In  $\mu$ DMA request (AES0 Cin)
- Context Out  $\mu$ DMA request (AES0 Cout)
- Data In  $\mu$ DMA request (AES0 Din)
- Data Out  $\mu$ DMA request (AES0 Dout)

The AES Module can be programmed to assert an interrupt when the uDMA has completed its last transfer. Please refer to “AES  $\mu$ DMA Interrupt Register Descriptions (CCM Offset)” on page 992 for more information.

If context and data transfers are to be handled through software, then the **AES Interrupt Enable (AES\_IRQENABLE)**, offset 0x090, can be used to enable interrupt triggering when context out, context in, data in or data out is ready. The **AES Interrupt Status (AES\_IRQSTATUS)**, offset 0x08C, indicates when an interrupt is triggered.

**Table 13-2. Interrupts and Events**

| Event                                      | Description              |
|--|--------------------------|
| <code>AES_IRQSTATUS[3]: CONTEXT_OUT</code> | Context output interrupt |
| <code>AES_IRQSTATUS[2]: DATA_OUT</code>    | Data output interrupt    |
| <code>AES_IRQSTATUS[1]: DATA_IN</code>     | Data input interrupt     |
| <code>AES_IRQSTATUS[0]: CONTEXT_IN</code>  | Context input interrupt  |

### 13.3 AES Performance Information

Table 13-3 on page 961 lists the performance for all supported key sizes and modes of operations. It assumes that the engine is kept fully utilized (that is, the host is supplying input blocks and retrieving output blocks in such a way that the engine never has to wait for input), and that the previous output has been retrieved before the next output is ready.

**Table 13-3. AES Module Performance (Input/Output Block Size = 128)**

| Key Size                  | Mode of Operation         | Cycles per Block <sup>a</sup> | Throughput (bits/cycle) |
|---------------------------|---------------------------|-------------------------------|-------------------------|
| 128                       | ECB-encrypt / decrypt     | 32                            | 4.00                    |
|                           | CBC-decrypt               |                               |                         |
|                           | CTR/ICM-encrypt / decrypt |                               |                         |
|                           | CFB128-decrypt            |                               |                         |
|                           | CBC-encrypt               | 33                            | 3.88                    |
|                           | OFB-encrypt / decrypt     |                               |                         |
|                           | f8-encrypt / decrypt      |                               |                         |
|                           | CFB128-encrypt            |                               |                         |
|                           | XTS-encrypt / decrypt     |                               |                         |
|                           | GCM-outbound / inbound    |                               |                         |
|                           | CCM-encrypt / decrypt     | 66                            | 1.94                    |
|                           | CBC-MAC <sup>b</sup>      | 33                            | 3.88                    |
|                           | f9 <sup>b</sup>           |                               |                         |
|                           | 192                       | ECB-encrypt / decrypt         | 38                      |
| CBC-decrypt               |                           |                               |                         |

**Table 13-3. AES Module Performance (Input/Output Block Size = 128) (continued)**

| Key Size | Mode of Operation         | Cycles per Block <sup>a</sup> | Throughput (bits/cycle) |
|----------|---------------------------|-------------------------------|-------------------------|
| 256      | ECB-encrypt / decrypt     | 44                            | 2.91                    |
|          | CBC-decrypt               |                               |                         |
|          | CTR/ICM-encrypt / decrypt |                               |                         |
|          | CFB128-decrypt            |                               |                         |
|          | CBC-encrypt               | 45                            | 2.84                    |
|          | OFB-encrypt / decrypt     |                               |                         |
|          | f8-encrypt / decrypt      |                               |                         |
|          | CFB128-encrypt            |                               |                         |
|          | XTS-encrypt / decrypt     |                               |                         |
|          | GCM-outbound inbound      | 90                            | 1.42                    |
|          | CCM-encrypt / decrypt     |                               |                         |
|          | CBC-MAC <sup>b</sup>      | 45                            | 2.84                    |
|          | f9 <sup>b</sup>           |                               |                         |

a. Standard Block Size (128 bits)

b. Input Only

The "Cycles per block" numbers do not apply to the first block after selection of a new key and/or mode of operation, or the last block before switching to a new algorithm. The next table indicates the additional clock cycles; required for changing context data.

**Table 13-4. AES Module Packet Mode Switch Overhead**

| New Context                       | Cycles needed for first block/and to finish the last block | Total |
|-----------------------------------|--|-------|
| mode is encrypt                   | 1 / 1  | 2     |
| mode is decrypt, key size is 128  | 32 / 1   | 33    |
| mode is decrypt, key size is 192  | 38 / 1   | 39    |
| mode is decrypt, key size is 256  | 44 / 1   | 45    |
| mode is XTS, key size is 128      | 34 / 1   | 35    |
| mode is XTS, key size is 192      | 40 / 1   | 41    |
| mode is XTS, key size is 256      | 46 / 1   | 47    |
| outbound GCM, AES key size is 128 | 33 <sup>a</sup> / 52                                       | 85    |
| outbound GCM, AES key size is 192 | 39 <sup>a</sup> / 52                                       | 91    |
| outbound GCM, AES key size is 256 | 45 <sup>a</sup> / 52                                       | 97    |
| inbound GCM, AES key size is 128  | 33 <sup>a</sup> / 27                                       | 60    |
| inbound GCM, AES key size is 192  | 39 <sup>a</sup> / 27                                       | 66    |
| inbound GCM, AES key size is 256  | 45 <sup>a</sup> / 27                                       | 72    |
| outbound CCM, AES key size is 128 | 33 <sup>b</sup> / 33                                       | 66    |
| outbound CCM, AES key size is 192 | 39 <sup>b</sup> / 39                                       | 78    |
| outbound CCM, AES key size is 256 | 45 <sup>b</sup> / 45                                       | 90    |
| inbound CCM, AES key size is 128  | 33 <sup>b</sup> / 33                                       | 66    |
| inbound CCM, AES key size is 192  | 39 <sup>b</sup> / 39                                       | 78    |

**Table 13-4. AES Module Packet Mode Switch Overhead (continued)**

| New Context                      | Cycles needed for first block/and to finish the last block | Total |
|----------------------------------|--|-------|
| inbound CCM, AES key size is 256 | 45 <sup>D</sup> / 45                                       | 90    |

a. Numbers for regular GCM mode (H is precalculated and Y0-encrypted need to be calculated internally using the new IV). If H needs to be calculated by the core (complete GCM mode), this number needs to be doubled. If Y0-encrypted is not calculated (forced to zero, such that the hash result is not encrypted) this number is zero.

b. Numbers for regular CCM mode. Dependent on the AAD length it is possible that one additional encryption needs to be done to finalize the AAD authentication; if the additional operation is required, this number needs to be doubled.

## 13.4 AES Module Programming Guide

### 13.4.1 AES Low - Level Programming Models

This section describes the low-level hardware programming sequences for configuring and using the AES Module.

#### 13.4.1.1 Global Initialization

The following list describes the requirements for initializing the AES and surrounding modules when AES is used for the first time after a device reset.

1. When reset has completed, enable the AES by setting the `R0` bit in the **CRC and Cryptographic Modules Run Mode Clock Gating Control (RCGCCM)**, System Control offset 0x674. When the `R0` bit is set in the **CRC and Cryptographic Modules Peripheral Ready (PRCCM)**, System Control offset 0xA74 register, the AES is powered and ready to be configured.
2. Configure the AES  $\mu$ DMA channels for Context In, Context Out, Data In, and/or Data Out by programming the appropriate encoding value in the **DMA Channel Map Select n (DMACHMAPn)** register in the  $\mu$ DMA module, offset 0x510. For more information on how to program channel assignments as well as enabling burst and the configured channels, refer to “Micro Direct Memory Access ( $\mu$ DMA)” on page 667.
3. Execute a software reset by setting the `SOFTRESET` bit in the **AES\_SYSCONFIG** register. When reset is complete, the `RESETDONE` bit reads as 1 in the **AES\_SYSSTATUS** register.
4. If the AES channels are configured in the  $\mu$ DMA, enable the required AES DMA requests by programming bits [9:5] of the **AES\_SYSCONFIG** register, in addition to the completion interrupts in the **AES DMA Interrupt Mask (AES\_DMAIM)** register, CCM offset 0x020.
5. Specify the size of the keys by programming the `KEY_SIZE` bit field in the **AES\_CTRL** register.
6. Load **AES Key 1 (AES\_KEY1\_n)** register.
7. Load **AES Key 2 (AES\_KEY2\_n)** register if it is used by the configuration mode. Refer to Table 13-6 on page 971 for information regarding which configuration modes require a load to this register.
8. Configure the AES for the appropriate encryption/decryption mode (see the section called “Subsequence: Initialize CCM AES Core Mode” on page 964 through the section called “Subsequence: Initialize CBC AES Core Mode” on page 965).
9. Select encryption or decryption by programming the `DIRECTION` bit in the **AES Control (AES\_CTRL)** register, offset 0x050.

### 13.4.1.2 Initialization Subsequence

The following sections list the initialization subsequences for the available encryption/decryption modes:

#### ***Subsequence: Initialize CCM AES Core Mode***

The CCM mode initialization is as follows:

1. Define the width of the length field and the length of the authentication field by programming the `CCM_L` and `CCM_M` bit fields in the **AES\_CTRL** register at offset 0x050.
2. Enable counter mode by setting the `CTR` bit in the **AES\_CTRL** register.
3. Load the authentication data length in the `AUTH` field of the **AES Authentication Data Length (AES\_AUTH\_LENGTH)** register at offset 0x05C.
4. Select the IV counter by programming the `CTR_WIDTH` field in the **AES\_CTRL** register.
5. Load the **AES Initialization Vector Input n (AES\_IV\_IN\_n)** registers at offset 0x040 to 0x04C.

#### ***Subsequence: Initialize GCM AES Core Mode***

The following steps to enable GCM mode is as follows:

1. Enable counter mode by setting the `CTR` bit in the **AES\_CTRL** register.
2. Load the authentication data length in the `AUTH` field of the **AES Authentication Data Length (AES\_AUTH\_LENGTH)** register at offset 0x05C.
3. Select the IV counter by programming the `CTR_WIDTH` field in the **AES\_CTRL** register.
4. Load the **AES Initialization Vector Input n (AES\_IV\_IN\_n)** registers at offset 0x040 to 0x04C.

#### ***Subsequence: Initialize CBC-MAC AES Core Mode***

To initialize CBC-MAC Mode:

1. Enable CBC-MAC Mode by setting the `CBCMAC` bit in the **AES\_CTRL** register.
2. Select encryption mode by setting the `DIRECTION` bit in the **AES\_CTRL** register at offset 0x050.
3. Load the **AES Initialization Vector Input n (AES\_IV\_IN\_n)** registers at offset 0x040 to 0x04C.

#### ***Subsequence: Initialize F9 AES Core Mode***

The steps for configuring the AES for F9 mode is as follows:

1. Enable F9 Mode by setting the `F9` bit in the **AES\_CTRL** register.
2. Set the key size to 128 bits by programming the `KEY_SIZE` field to 0x1 in the **AES\_CTRL** register.
3. Load the **AES Initialization Vector Input n (AES\_IV\_IN\_n)** registers at offset 0x040 to 0x04C.

#### ***Subsequence: Initialize F8 AES Core Mode***

The steps for configuring the AES for F8 mode is as follows:

1. Enable F8 Mode by setting the F8 bit in the **AES\_CTRL** register.
2. Select the counter width by programming the **CTR\_WIDTH** field in the **AES\_CTRL** register.
3. Set the key size to 128 bits by setting the **KEY\_SIZE** field to 0x1 in the **AES\_CTRL** register.
4. Load the **AES Initialization Vector Input n (AES\_IV\_IN\_n)** registers at offset 0x040 to 0x04C.

**Subsequence: Initialize XTS AES Core Mode**

The steps for XTS mode configuration are as follows:

1. Enable XTS Mode by configuring the **XTS** field in the **AES\_CTRL** register.
2. If the **XTS** field in the **AES\_CTRL** register indicates that the AAD length is required, load the AAD length in the **AES\_AUTH\_LENGTH** register.
3. Load the **AES Initialization Vector Input n (AES\_IV\_IN\_n)** registers at offset 0x040 to 0x04C.

**Subsequence: Initialize CFB AES Core Mode**

To initialize the AES code for CFB mode:

1. Enable CFB Mode by setting the **CFB** bit in the **AES\_CTRL** register.
2. Load the **AES Initialization Vector Input n (AES\_IV\_IN\_n)** registers at offset 0x040 to 0x04C.

**Subsequence: Initialize ICM AES Core Mode**

To initialize the AES code for ICM mode:

1. Enable ICM Mode by setting the **ICM** bit in the **AES\_CTRL** register.
2. Configure for a 16-bit counter by programming the **CTR\_WIDTH** to 0x0 in the **AES\_CTRL** register.
3. Load the **AES Initialization Vector Input n (AES\_IV\_IN\_n)** registers at offset 0x040 to 0x04C.

**Subsequence: Initialize CTR AES Core Mode**

To initialize CTR mode:

1. Enable CTR Mode by setting the **CTR** bit in the **AES\_CTRL** register.
2. Select counter width by programming the **CTR\_WIDTH** in the **AES\_CTRL** register.
3. Load the **AES Initialization Vector Input n (AES\_IV\_IN\_n)** registers at offset 0x040 to 0x04C.

**Subsequence: Initialize CBC AES Core Mode**

To configure CBC mode:

1. Enable CBC Mode by setting the **MODE** bit in the **AES\_CTRL** register.
2. Load the **AES Initialization Vector Input n (AES\_IV\_IN\_n)** registers at offset 0x040 to 0x04C.

### 13.4.1.3 Operational Modes Configuration

#### AES Polling Mode

##### Main Sequence: AES Polling Mode

Figure 13-12 on page 966 shows AES polling mode. The registers used in AES polling mode are:

- AES Data RW Plaintext/Ciphertext 0 (AES\_DATA\_IN\_0) registers, offset 0x060 to 0x06C
- AES Control (AES\_CTRL) register, offset 0x050
- AES Hash Tag Out 0 (AES\_TAG\_OUT\_0), offset 0x070

Figure 13-12. AES Polling Mode

#### AES Interrupt Mode

The application can use software interrupts to control the flow of Context In, Context Out, Data In, and Data Out requests. To enable these interrupts:

1. Once the device has been initialized, following the initialization sequences described in “Global Initialization” on page 963 and “Initialization Subsequence” on page 964, the application can enable the AES module interrupts through the **AES Interrupt Enable (AES\_IRQENABLE)** register, offset 0x090. If all four interrupts must be enabled, the application can write 0x0000.000F to the **AES\_IRQENABLE** register.
2. Load the input buffers, **AES\_DATA\_IN\_n**, with data.

**Note:** If the application uses Interrupt Mode, an interrupt is generated for each block of processed data. To support larger data flow, AES  $\mu$ DMA Mode should be used and the bits in the **AES\_IRQENABLE** register should be cleared.

#### **AES DMA Mode**

When AES DMA Mode is enabled, the **AES\_IRQENABLE** register should be cleared. To enable the  $\mu$ DMA to transfer data follow these steps:

1. Once the AES module has been initialized, enable the AES module  $\mu$ DMA channels by programming the **DMA Channel Map Select n (DMACHMAPn)** register in the  $\mu$ DMA module. Further  $\mu$ DMA configuration guidelines are available in the “Micro Direct Memory Access ( $\mu$ DMA)” on page 667.
2. Configure the dma\_done interrupts by programming the **AES DMA Masked Interrupt Status (AES\_DMAMIS)** register, at CCM offset 0x028.
3. Enable the  $\mu$ DMA channels in the AES by programming the  $\mu$ DMA enable bits in the **AES System Configuration (AES\_SYSCONFIG)** register, offset 0x084.
4. The input buffer registers, **AES\_DATA\_IN\_n**, at offsets 0x060 to 0x06C, are loaded.

#### **13.4.1.4 AES Events Servicing**

##### **Interrupt Servicing**

This section describes the event servicing of the module. Figure 13-13 on page 968 shows the AES interrupt service. The registers used during event servicing are:

- **AES\_IRQSTATUS**
- **AES\_KEY1\_n**
- **AES\_KEY2\_n**
- **AES\_IV\_IN\_n**
- **AES\_DATA\_IN\_n**
- **AES\_TAG\_OUT\_n**
- **AES\_IRQENABLE**

Figure 13-13. AES Interrupt Service

### 13.5 Register Map

Table 13-5 on page 968 lists the AES registers. The AES Module comprises registers that exist at an offset relative to the AES Module base address and a small set of AES  $\mu$ DMA registers that exist at an offset relative to an Encryption Control Module base address. The AES Module register offsets are relative to the base address 0x4403.6000. The AES  $\mu$ DMA interrupt registers are offset relative to the base address 0x4403.0000.

Table 13-5. AES Register Map

| Offset  | Name       | Type | Reset       | Description | See page |
|---|------------|------|-------------|-------------|----------|
| <b>AES Module Registers (AES Module Offset)</b> |            |      |             |             |          |
| 0x000   | AES_KEY2_6 | RW   | 0x0000.0000 | AES Key 2_6 | 971      |
| 0x004   | AES_KEY2_7 | RW   | 0x0000.0000 | AES Key 2_7 | 971      |
| 0x008   | AES_KEY2_4 | RW   | 0x0000.0000 | AES Key 2_4 | 971      |

Table 13-5. AES Register Map (continued)

| Offset | Name            | Type | Reset       | Description                        | See page |
|--------|-----------------|------|-------------|------------------------------------|----------|
| 0x00C  | AES_KEY2_5      | RW   | 0x0000.0000 | AES Key 2_5                        | 971      |
| 0x010  | AES_KEY2_2      | RW   | 0x0000.0000 | AES Key 2_2                        | 971      |
| 0x014  | AES_KEY2_3      | RW   | 0x0000.0000 | AES Key 2_3                        | 971      |
| 0x018  | AES_KEY2_0      | RW   | 0x0000.0000 | AES Key 2_0                        | 971      |
| 0x01C  | AES_KEY2_1      | RW   | 0x0000.0000 | AES Key 2_1                        | 971      |
| 0x020  | AES_KEY1_6      | RW   | 0x0000.0000 | AES Key 1_6                        | 971      |
| 0x024  | AES_KEY1_7      | RW   | 0x0000.0000 | AES Key 1_7                        | 971      |
| 0x028  | AES_KEY1_4      | RW   | 0x0000.0000 | AES Key 1_4                        | 971      |
| 0x02C  | AES_KEY1_5      | RW   | 0x0000.0000 | AES Key 1_5                        | 971      |
| 0x030  | AES_KEY1_2      | RW   | 0x0000.0000 | AES Key 1_2                        | 971      |

## 13.6 AES Register Descriptions

This section lists and describes the AES registers, in numerical order by address offset.

- Register 1: AES Key 2\_6 (AES\_KEY2\_6), offset 0x000**
- Register 2: AES Key 2\_7 (AES\_KEY2\_7), offset 0x004**
- Register 3: AES Key 2\_4 (AES\_KEY2\_4), offset 0x008**
- Register 4: AES Key 2\_5 (AES\_KEY2\_5), offset 0x00C**
- Register 5: AES Key 2\_2 (AES\_KEY2\_2), offset 0x010**
- Register 6: AES Key 2\_3 (AES\_KEY2\_3), offset 0x014**
- Register 7: AES Key 2\_0 (AES\_KEY2\_0), offset 0x018**
- Register 8: AES Key 2\_1 (AES\_KEY2\_1), offset 0x01C**
- Register 9: AES Key 1\_6 (AES\_KEY1\_6), offset 0x020**
- Register 10: AES Key 1\_7 (AES\_KEY1\_7), offset 0x024**
- Register 11: AES Key 1\_4 (AES\_KEY1\_4), offset 0x028**
- Register 12: AES Key 1\_5 (AES\_KEY1\_5), offset 0x02C**
- Register 13: AES Key 1\_2 (AES\_KEY1\_2), offset 0x030**
- Register 14: AES Key 1\_3 (AES\_KEY1\_3), offset 0x034**
- Register 15: AES Key 1\_0 (AES\_KEY1\_0), offset 0x038**
- Register 16: AES Key 1\_1 (AES\_KEY1\_1), offset 0x03C**

This register contains the 32-bit key data for the AES module. This value can be expanded to 256-bits depending on the mode of operation. Table 13-6 on page 971 describes the type of key that is held in register.

**Note:** Reads return zeros.

**Table 13-6. AES Key Register Descriptions**

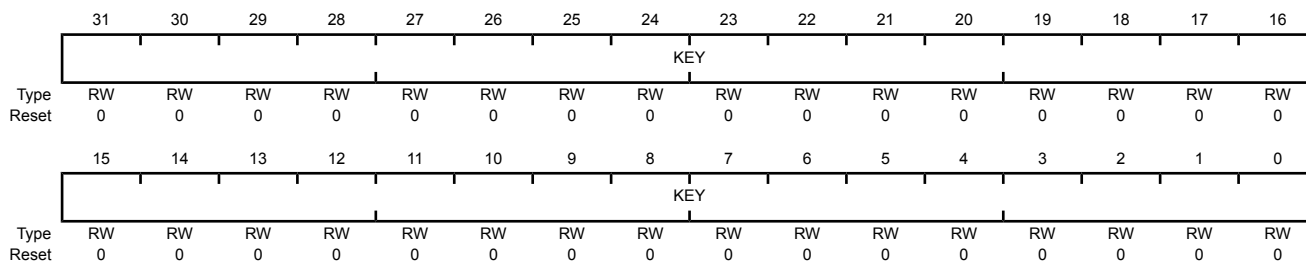

| Register Name | Address Offset | Description   |
|---------------|----------------|---|
| AES_KEY2_6    | 0x000          | Secure XTS second key / CBC-MAC third key   |
| AES_KEY2_7    | 0x004          | Secure XTS second key (MSW for 256-bit key) / CBC-MAC third key (MSW)                             |
| AES_KEY2_4    | 0x008          | Secure XTS / CCM second key / CBC-MAC third key (LSW)   |
| AES_KEY2_5    | 0x00C          | Secure XTS second key (MSW for 192-bit key) / CBC-MAC third key                                   |
| AES_KEY2_2    | 0x010          | Secure XTS / CCM / CBC-MAC second key / Hash Key input  |
| AES_KEY2_3    | 0x014          | Secure XTS second key (MSW for 128-bit key) + CCM/CBC-MAC second key (MSW) / Hash Key input (MSW) |
| AES_KEY2_0    | 0x018          | Secure XTS / CCM / CBC-MAC second key (LSW) / Hash Key input (LSW)                                |
| AES_KEY2_1    | 0x01C          | Secure XTS / CCM / CBC-MAC second key / Hash Key input  |
| AES_KEY1_6    | 0x020          | Secure Key (LSW for 256-bit key)  |
| AES_KEY1_7    | 0x024          | Secure Key (MSW for 256-bit key)  |
| AES_KEY1_4    | 0x028          | Secure Key (LSW for 192-bit key)  |
| AES_KEY1_5    | 0x02C          | Secure Key (MSW for 192-bit key)  |

**Table 13-6. AES Key Register Descriptions (continued)**

| Register Name | Address Offset | Description                      |
|---------------|----------------|----------------------------------|
| AES_KEY1_2    | 0x030          | Secure Key                       |
| AES_KEY1_3    | 0x034          | Secure Key (MSW for 128-bit key) |
| AES_KEY1_0    | 0x038          | Secure Key (LSW for 128-bit key) |
| AES_KEY1_1    | 0x03C          | Secure Key                       |

AES Key (AES\_KEYn\_n)

Base 0x4403.6000  
 Offset 0x000  
 Type RW, reset 0x0000.0000

| Bit/Field | Name | Type | Reset      | Description  |
|-----------|------|------|------------|--|
| 31:0      | KEY  | RW   | 0x00000000 | Key Data<br>This register contains the 32-bit key data for the AES module. |

**Register 17: AES Initialization Vector Input 0 (AES\_IV\_IN\_0), offset 0x040**

**Register 18: AES Initialization Vector Input 1 (AES\_IV\_IN\_1), offset 0x044**

**Register 19: AES Initialization Vector Input 2 (AES\_IV\_IN\_2), offset 0x048**

**Register 20: AES Initialization Vector Input 3 (AES\_IV\_IN\_3), offset 0x04C**

This register contains the initialization vector input.

AES Initialization Vector Input (AES\_IV\_IN\_n)

Base 0x4403.6000

Offset 0x040

Type RW, reset 0x0000.0000

| Bit/Field | Name | Type | Reset       | Description  |
|-----------|------|------|-------------|--|
| 31:0      | DATA | RW   | 0x0000.0000 | Initialization Vector Input<br>This field contains the initialization input vector. The least significant word (LSW) is represented in register <b>AES_IV_IN_0</b> and the most significant word is stored in <b>AES_IV_IN_3</b> |

## Register 21: AES Control (AES\_CTRL), offset 0x050

This register determines the mode of operation of the AES Engine.

### AES Control (AES\_CTRL)

Base 0x4403.6000  
 Offset 0x050  
 Type RW, reset 0x8000.0000

| Reset | 0       | 0         | 0            | 0        | 0   | 0   | 0         | 0     | 0    | 0        | 0     | 0  | 0         | 0           | 0            | 0  |

| Bit/Field | Name         | Type | Reset | Description   |
|-----------|--------------|------|-------|---|
| 31        | CTXTRDY      | RO   | 1     | Context Data Registers Ready  |
|           |              |      |       | Value Description   |
|           |              |      |       | 0 The context data registers are not ready to be overwritten.   |
|           |              |      |       | 1 The context data registers can be overwritten and the host is permitted to write the next context.  |
| 30        | SVCTXTRDY    | RO   | 0     | AES TAG/IV Block(s) Ready   |
|           |              |      |       | <b>Note:</b> This bit is only asserted if the SAVE_CONTEXT bit is set to 1. This bit is mutual exclusive with the CTXTRDY bit.                              |
|           |              |      |       | Value Description   |
|           |              |      |       | 0 AES authentication TAG and/or IV block(s) is/are not available.   |
|           |              |      |       | 1 Indicates the AES authentication TAG and /or IV block(s) is/are available for the host to retrieve.   |
| 29        | SAVE_CONTEXT | RW   | 0     | TAG or Result IV Save   |
|           |              |      |       | If this bit is set, the CONTEXT_OUT interrupt bit is set in the <b>AES_IRQSTATUS</b> register if the operation is finished and related signals are enabled. |
|           |              |      |       | Value Description   |
|           |              |      |       | 0 No effect.  |
|           |              |      |       | 1 Indicates an authentication TAG of result IV needs to be stored as a result context.  |

| Bit/Field | Name   | Type | Reset | Description   |       |             |     |                              |     |  |     |  |     |  |           |          |     |           |
|-----------|--|------|-------|---|-------|-------------|-----|------------------------------|-----|--|-----|--|-----|--|-----------|----------|-----|-----------|
| 28:25     | reserved   | R    | 0     | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.   |       |             |     |                              |     |  |     |  |     |  |           |          |     |           |
| 24:22     | CCM_M  | RW   | 0     | Counter with CBC-MAC (CCM)<br>Defines M which indicates the length of the authentication field for CCM operations; the authentication field length equals two times the sum of CCM-M plus one.<br><br><b>Note:</b> The AES Engine always returns a 128-bit authentication field, of which the M least significant bytes are valid. All values are supported.  |       |             |     |                              |     |  |     |  |     |  |           |          |     |           |
| 21:19     | CCM_L  | RW   | 0     | L Value<br>Defines L, which indicates the width of the length field for CCM operations; the length field in bytes equals the value of CMM-L plus one. Supported values for L are:<br><br><table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>width = 0</td> </tr> <tr> <td>0x1</td> <td>width = 2</td> </tr> <tr> <td>0x2</td> <td>reserved</td> </tr> <tr> <td>0x3</td> <td>width = 4</td> </tr> <tr> <td>0x4 - 0x6</td> <td>reserved</td> </tr> <tr> <td>0x7</td> <td>width = 8</td> </tr> </tbody> </table>   | Value | Description | 0x0 | width = 0                    | 0x1 | width = 2  | 0x2 | reserved   | 0x3 | width = 4  | 0x4 - 0x6 | reserved | 0x7 | width = 8 |

**Register 22: AES Crypto Data Length 0 (AES\_C\_LENGTH\_0), offset 0x054****Register 23: AES Crypto Data Length 1 (AES\_C\_LENGTH\_1), offset 0x058**

**AES Crypto Data Length n (AES\_C\_LENGTH\_n)** registers (LSW and MSW) store the cryptographic data length in bytes for all modes. The **AES\_C\_LENGTH\_0** register stores the most significant word and the **AES\_C\_LENGTH\_1** register stores the least significant word. Once processing with this context is started, this length decrements to zero. Data lengths up to  $(2^{61} - 1)$  bytes are allowed. For GCM, any value up to 236 - 32 bytes can be used. This is because a 32-bit counter mode is used; the maximum number of 128-bit blocks is  $2^{32} - 2$ , resulting in a maximum number of bytes of  $2^{36} - 32$ . A write to this register triggers the engine to start using this context. This is valid for all modes except GCM and CCM. Note that for the combined modes, this length does not include the authentication only data; the authentication length is specified in the **AES\_AUTH\_LENGTH** register below. All modes must have a length greater than 0. For the combined modes, it is permissible to have one of the lengths equal to zero. For the basic encryption modes (ECB/CBC/CTR/ICM/CFB128) it is permissible to program zero to the length field; in that case the length is assumed infinite. All data must be byte (8-bit) aligned; bit aligned data streams are not supported by the AES Engine.

**Note:** For a Host read operation, these registers return all zeroes.

## AES Crypto Data Length (AES\_C\_LENGTH\_n)

Base 0x4403.6000  
Offset 0x054

| 31:0      | LENGTH | RW   | 0x00000000 | Data Length<br>This field stores the cryptographic data length in bytes for all modes. |

### Register 24: AES Authentication Data Length (AES\_AUTH\_LENGTH), offset 0x05C

The **AES Authentication Data Length (AES\_AUTH\_LENGTH)** register stores the authentication data length in bytes for combined modes only (GCM or CCM). Supported `AUTH` lengths for CCM are from 0 to  $(2^{16} - 28)$  bytes. For GCM any value up to  $(2^{32} - 1)$  bytes can be used. Once processing with this context is started, this length decrements to zero. A write to this register triggers the engine to start using this context for GCM and CCM. For XTS, this register is optionally used to load `j`. Loading of `j` is only required if `j`  $\neq$  0. `j` is a 28-bit value and must be written to bits [31-4] of this register. `j` represents the sequential number of the 128-bit block inside the data unit. For the first block in a unit, this value is zero. It is not required to provide a `j` for each new data block within a unit. Note that it is possible to start with a `j` unequal to zero.

**Note:** For a Host read operation, these registers return all-zeroes..

#### AES Authentication Data Length (AES\_AUTH\_LENGTH)

Base 0x4403.6000  
 Offset 0x05C  
 Type RW, reset 0x0000.0000

| Bit/Field | Name | Type | Reset      | Description  |

**Register 25: AES Data RW Plaintext/Ciphertext 0 (AES\_DATA\_IN\_0), offset 0x060**

**Register 26: AES Data RW Plaintext/Ciphertext 1 (AES\_DATA\_IN\_1), offset 0x064**

**Register 27: AES Data RW Plaintext/Ciphertext 2 (AES\_DATA\_IN\_2), offset 0x068**

**Register 28: AES Data RW Plaintext/Ciphertext 3 (AES\_DATA\_IN\_3), offset 0x06C**

The **AES Data RW Plaintext/Ciphertext n (AES\_DATA\_IN\_n)** registers are used to read and write plaintext/ciphertext. The **AES\_DATA\_IN\_0** register contains the most significant word; the **AES\_DATA\_IN\_3** register contains least significant word.

**Note:** The **AES\_DATA\_IN\_0** register acts as a FIFO and shifts data into the other **AES\_DATA\_IN\_n** registers.

|           |            |      |       | Value Description   |
|           |            |      |       | 0 The context in interrupt is not active.   |
|           |            |      |       | 1 The context in interrupt is active and the interrupt output has been triggered. |

### Register 37: AES Interrupt Enable (AES\_IRQENABLE), offset 0x090

This register contains an enable bit for each unique interrupt generated by the module. It matches the layout of **AES\_IRQSTATUS** register. An interrupt is enabled when the bit in this register is set to 1. An interrupt that is enabled is propagated to the NVIC controller. All AES software interrupts need to be enabled explicitly by writing this register.

**Note:** If the application uses Interrupt Mode, an interrupt is generated for each block of processed data. To support larger data flow, AES  $\mu$ DMA Mode should be used and the bits in the **AES\_IRQENABLE** register should be cleared.

#### AES Interrupt Enable (AES\_IRQENABLE)

Base 0x4403.6000  
 Offset 0x090

## 13.7 AES µDMA Interrupt Register Descriptions (CCM Offset)

This section lists and describes the AES µDMA registers, in numerical order by address offset. Registers in this section are relative to the base address of 0x4403.0000.

**Register 39: AES DMA Interrupt Mask (AES\_DMAIM), offset 0x020**

The **AES DMA Interrupt Mask (AES\_DMAIM)** register controls interrupt behavior and is used to program which interrupts are suppressed.

**AES DMA Interrupt Mask (AES\_DMAIM)**

### Register 42: AES DMA Interrupt Clear (AES\_DMAIC), offset 0x02C

The **AES DMA Interrupt Clear (AES\_DMAIC)** register is used to clear the **AES\_DMARIS** and **AES\_DMAMIS** registers by writing a 1 to each register bit.

**Note:** This registers always reads as zero.

#### AES DMA Interrupt Clear (AES\_DMAIC)

## 14 Data Encryption Standard Accelerator (DES)

The DES module provides hardware accelerated data encryption and decryption functions. The module runs either the single DES or the triple DES (3DES) algorithm in compliance with the [FIPS 46-3 standard](#) and supports electronic codebook (ECB), cipher block chaining (CBC), and cipher feedback (CFB) modes of operation. It does not support the output feedback (OFB) mode of operation in hardware.

The purpose of the DES algorithm is to encrypt (encipher) or decrypt (decipher) binary coded information. Encrypting data converts it to an unintelligible form called cipher text. Decrypting cipher text converts the data back to its original form called plaintext. DES is a symmetrical algorithm in that the encryption and decryption keys are identical. Each triple DES encrypt/decrypt operation is a compound of DES encrypt and decrypt operations.

The DES accelerator includes the following main features:

- DES/3DES encryption and decryption.
- Feedback modes: ECB, CBC, CFB
- Host interrupt or  $\mu$ DMA driven modes of operation.  $\mu$ DMA support for data and context in/result out
- Fully synchronous design
- Internal wide-bus interface

### 14.1 DES Functional Description

The DES module is an efficient implementation of a DES block cipher. Block ciphers, as opposed to stream ciphers, operate on blocks of plain text and cipher text. The DES block size is 8-byte. The DES key consists of 64 binary digits, but only 56 bits are actually used directly by the algorithm. The other 8 bits are used for error detection.

The 64-bit block of input data to be enciphered is initially permuted, then passed through 16 iterations of a calculation that uses a cipher function and finally permuted to the inverse of the initial permutation. At each of the 16 iterations, a 48-bit key computed from the 64-bit input key is applied to one of the 32-bit sub-blocks of the 64-bit input block using the cipher function. The 48-bit key value changes for each iteration. The result of the cipher function is a 32-bit sub-block, which is concatenated with the second 32-bit input sub-block. The resulting 64-bit output block of each iteration feeds back as the input of the next iteration. To decipher, it is only necessary to apply the same algorithm to the enciphered message block, taking care that each iteration of the computation will use the same 48-bit key which was used during enciphering.

The triple DES is the DES used three times in a row (also known as DES-EDE). It uses three keys key1, key2, and key3, so that key length is 168 bits effective: a 64-bit block plaintext is encrypted with key1, decrypted with key2, and encrypted with key3, and a 64-bit ciphertext is decrypted with key1, encrypted with key2, and decrypted with key3.

There are three keying options defined in ANSI X9.52 for DES-EDE:

- The three keys key1, key2, and key3 are independent.
- key1 and key2 are independent, but key1 = key3
- key1 = key2 = key3

The first option provides highest level of security; the last option is compatible with single DES. See Table 14-1 on page 1000 for key use.

**Table 14-1. Key Repartition**

| Mode           | Key1_L | Key1_H | Key2_L | Key2_H | Key3_L | Key3_H |
|----------------|--------|--------|--------|--------|--------|--------|
| 64-bit (DES)   | √      | √      | X      | X      | X      | X      |
| 192-bit (3DES) | √      | √      | √      | √      | √      | √      |

ECB, CBC, and CFB modes can be used with DES and 3DES modes.

## 14.2 DES Block Diagram

The module architecture consists of primary blocks, as shown in Figure 14-1 on page 1000. The DES module includes a register interface, and a  $\mu$ DMA and interrupt interface.

Depending of the availability of context and data, the DES engine is automatically triggered to process the data. The DES engine is directly connected to the context and data registers such that it can immediately start processing when all data is available.

Packets (blocks of 64 bits) must be parsed into blocks and sequentially fed into the DES, which can buffer the block currently being processed as well as an additional block that may be queued in advance.

**Figure 14-1. DES Block Diagram**

### 14.2.1 $\mu$ DMA Control

The  $\mu$ DMA and interrupt request logic is controlled by the DES Engine. The DES Engine can have multiple  $\mu$ DMA request signals active in parallel.

There are three DMA channels available:

- DMA context in - Request a new context (DES0 Cin)
- DMA data in - Request input data (DES0 Din)
- DMA data out - Request output data read (DES0 Dout)

### 14.2.2 Interrupt Control

There is one interrupt for the DES that is sent to the interrupt controller. This interrupt is an OR of the enabled interrupt bits in the **DES Interrupt Status (DES\_IRQSTATUS)** register. These bits are enabled through the **DES Interrupt Enable (DES\_IRQENABLE)** register. The following events can generate an interrupt bit to be set in the **DES\_IRQSTATUS** register. These are:

- New context input required
- Data input required
- Data output ready

### 14.2.3 Register Interface

The Register Interface block performs all address decoding and control; however, not all registers are available in this block. The context and data input registers are in the DES engine.

### 14.2.4 DES Engine

The DES buffered engine consists of the following major functional blocks:

- Cipher core: the DES algorithm
- Mode control FSM: manages the data flow to and from the DES buffered engine and starts each encrypt/decrypt operation
- DES feedback mode block: the logic that implements the various feedback modes supported by the DES buffered engine

#### 14.2.4.1 Mode Control FSM

The Mode control FSM manages the data flow to and from the DES engine. This block also sends a start pulse to the encrypt/decrypt core and triggers the core to use the new mode keys when a new context is needed. This module also controls the 3DES operation, such that the DES core module is triggered three times (with different keys) before the result data becomes available.

#### 14.2.4.2 DES Feedback Mode Block

The DES feedback mode block buffers the input and output blocks and contains all logic to implement the 3DES and various feedback modes. See the FIPS-81 document for details on the ECB, CBC, and CFB modes of operation.

By itself, the DES cipher core outputs data compliant for ECB encryption. However, most applications use DES with feedback. Feedback provides additional security by randomizing repeated patterns in the plain text, which could otherwise be exploited to attack the cipher text. The DES buffered engine supports ECB, CBC, and CFB modes of operations for the DES and 3DES algorithm.

3DES mode performs the DES algorithm three times on a single block and uses a different key for each invocation of the DES algorithm, greatly increasing security of the cipher text but at the cost

of a 3x reduction in throughput. The DES buffered engine implements a 3DES logic wrapper around the 2-round DES core, enabling seamless 3DES encryption.

#### 14.2.4.3 DES Cipher Core

The DES cipher core implements the DES algorithm as specified in the FIPS 46-3. The core operates on the input block and performs the required substitution, shift, and mix operations. The core also applies the correct key-scheduling.

Inherently, considerable parallelism is possible with the DES algorithm. This is exploited in two ways. For high performance, the 64 bits composing the data block are processed concurrently (4-round implementation). For low gate-count, resources are shared on both the main data and key paths (1-round implementation).

A fundamental component of the DES algorithm is the substitution box (S-Box). The S-Box provides a unique 4-bit output for each 6-bit input. The S-Box design is a primary factor for both performance and gate count. The DES Cipher Core has a standard lookup table S-Box that allows room for the synthesizer to optimize on timing or gate count.

### 14.3 Software Reset

Table 14-2 on page 1002 lists the resets used in the DES module.

**Table 14-2. DES Reset Description**

| Type     | Name                           | Source   | Description   |
|----------|--------------------------------|----------|---|
| Hardware | DES_RST                        | PRCM     | Global reset  |
| Software | DES_SYSCONFIG [1]<br>SOFTRESET | Internal | Starts the soft reset sequence. When the DES_SYSSTATUS/DES_P_SYSSTATUS[0] RESETDONE bit goes to 1, the soft reset sequence is finished. |

### 14.4 DES Supported Modes of Operation

#### 14.4.1 ECB Feedback Mode

Figure 14-2 on page 1003 shows the basic ECB feedback mode of operation, where the input data is passed directly to the basic cryptographic core and the output of the cryptographic core is passed directly to the output buffer. For decryption the DES core operates in reverse, this means the decrypt key sequence is used for the data processing, where encryption uses the encrypt key sequence.

Figure 14-2. DES - ECB Feedback Mode

#### 14.4.1.1 CBC Feedback Mode

Figure 14-3 on page 1003 shows the CBC feedback mode of operation, where the input data is XORed with the initialization vector (IV) before it is passed to the basic crypto core. The output of the crypto core is passed directly to the output buffer. For decryption the operation is reversed, resulting in an XOR at the output of the crypto core.

Figure 14-3. DES3DES - CBC Feedback Mode

#### 14.4.1.2 CFB Feedback Mode

Figure 14-4 on page 1004 shows the CFB mode of operation for encryption and decryption. The input for the crypto core is the IV; the result is XORed with the data. The result is fed back via the IV register, as the next input for the crypto core. The decrypt operation is reversed, but the crypto core is still performing an encryption.

Figure 14-4. DES3DES-CFB Feedback Mode

## 14.5 DES Module Programming Guide -Low Level Programming Models

### 14.5.1 Surrounding Modules Global Initialization

#### 14.5.1.1 Main Sequence - DES Global Initialization

This procedure initializes the DES after a POR.

Table 14-3. DES Global Initialization

| Step   | Register/Bit Field/Programming Model | Value |
|--|--------------------------------------|-------|
| Execute software reset.                      | DES_SYSCONFIG[1] SOFTRESET           | 0x1   |
| Wait for reset to complete                   | DES_SYSSTATUS[0] RESETDONE           | = 0x1 |
| Select force idle mode                       | DES_SYSCONFIG[3:2] SIDLE             | 0x0   |
| Select the algorithm type (DES or 3DES)      | See the programming models           |       |
| Select the operating mode (ECB, CBC or CFB). | DES_CTRL[5:4] MODE                   | -     |
| IF: ECB operating mode not selected.         | DES_CTRL[5:4] MODE                   | ≠ 0x0 |
| Load the initialization vector LSW.          | DES_IV_L[31:0] IV_L                  | -     |
| Load the initialization vector MSW.          | DES_IV_H[31:0] IV_H                  | -     |
| Define the cryptographic data length.        | DES_LENGTH[31:0] LENGTH              | -     |
| ENDIF  |                                      |       |
| Select encryption or decryption.             | DES_CTRL[2] DIRECTION                | -     |

#### 14.5.1.2 Subsequence - Configure the DES Algorithm Type

This subsequence details the DES algorithm type settings.

**Table 14-4. DES Algorithm Type Configuration**

| Step                  | Register/Bit Field/Programming Model | Value |
|-----------------------|--------------------------------------|-------|
| Load key 1 LSW.       | DES_KEY1_L[31:0] KEY1_L              | -     |
| Load key 1 MSW.       | DES_KEY1_H[31:0] KEY1_H              | -     |
| Select DES algorithm. | DES_CTRL[3] TDES                     | 0x0   |

### 14.5.1.3 Subsequence - Configure the 3DES Algorithm Type

This subsequence details the 3DES algorithm type settings.

**Table 14-5. 3DES Algorithm Type Configuration**

| Step                   | Register/Bit Field/Programming Model | Value |
|------------------------|--------------------------------------|-------|
| Load key 1 LSW.        | DES_KEY1_L[31:0] KEY1_L              | -     |
| Load key 1 MSW.        | DES_KEY1_H[31:0] KEY1_H              | -     |
| Load key 2 LSW.        | DES_KEY2_L[31:0] KEY2_L              | -     |
| Load key 2 MSW.        | DES_KEY2_H[31:0] KEY2_H              | -     |
| Load key 3 LSW.        | DES_KEY3_L[31:0] KEY3_L              | -     |
| Load key 3 MSW.        | DES_KEY3_H[31:0] KEY3_H              | -     |
| Select 3DES algorithm. | DES_CTRL[3] TDES                     | 0x1   |

## 14.5.2 Operational Modes Configuration

### 14.5.2.1 Main Sequence - DES Polling Mode

Figure 14-5 on page 1006 shows DES polling mode. The registers used in DES polling mode are: DES\_DATA\_L, DES\_DATA\_H, and DES\_CTRL.

Figure 14-5. DES Polling Mode

### 14.5.2.2 DES Interrupt Mode

Table 14-6 on page 1006 lists the DES interrupt mode steps.

Table 14-6. DES Interrupt Mode

| Step                                     | Register/Bit Field/Programming Model | Value |
|--|--------------------------------------|-------|
| Enable DES module interrupts.            | DES_IRQENABLE[2:0]                   | 0x7   |
| Load the input buffer data LSW register. | DES_DATA_L[31:0] DATA_L              | -     |
| Load the input buffer data HSW register. | DES_DATA_H[31:0] DATA_H              | -     |

### 14.5.2.3 DES Interrupt DMA Mode

Table 14-7 on page 1006 lists the DES DMA mode steps.

Table 14-7. DES DMA Mode

| Step                                     | Register/Bit Field/Programming Model | Value |
|--|--------------------------------------|-------|
| Enable DES module DMA requests.          | DES_SYSCONFIG[7:5]                   | 0x7   |
| Load the input buffer data LSW register. | DES_DATA_L[31:0] DATA_L              | -     |

Table 14-7. DES DMA Mode (continued)

| Step                                     | Register/Bit Field/Programming Model | Value |
|--|--------------------------------------|-------|
| Load the input buffer data HSW register. | DES_DATA_H[31:0] DATA_H              | -     |

### 14.5.3 DES Events Servicing

#### 14.5.3.1 Interrupt Servicing

This section describes the event servicing of the module. Figure 14-6 on page 1007 shows the DES interrupt service. The registers used during event servicing are: DES\_IRQSTATUS, DES\_DATA\_L, and DES\_DATA\_H.

Figure 14-6. DES Interrupt Service

#### 14.5.3.2 Context Input Event Servicing

This section describes the context input event servicing of the module, as shown in Figure 14-7 on page 1008. The registers used during event servicing are: DES\_CTRL, DES\_SYSCONFIG, DES\_KEY1\_L, DES\_KEY1\_H, DES\_KEY2\_L, DES\_KEY2\_H, DES\_KEY3\_L, DES\_KEY3\_H, DES\_IV\_L, DES\_IV\_H, and DES\_LENGTH.

Figure 14-7. DES Context Input Event Service

## 14.6 Register Map

Table 14-8 on page 1008 lists the DES registers. The DES Module comprises registers that exist at an offset relative to the DES Module base address and a small set of DES  $\mu$ DMA registers that exist at an offset relative to an Encryption Control Module base address. The DES Module register offsets are relative to the base address 0x4403.8000. The Encryption Control register offsets are relative to the base address 0x4403.0000.

**Note:** The DES registers are limited to 32-bit data accesses; 8- and 16-bit accesses are not allowed and can corrupt register contents.

Table 14-8. DES Register Map

| Offset  | Name       | Type | Reset       | Description                   | See page |
|---|------------|------|-------------|-------------------------------|----------|
| <b>DES Module Registers (DES Module Offset)</b> |            |      |             |                               |          |
| 0x000   | DES_KEY3_L | RW   | 0x0000.0000 | DES Key 3 LSW for 192-Bit Key | 1010     |
| 0x004   | DES_KEY3_H | RW   | 0x0000.0000 | DES Key 3 MSW for 192-Bit Key | 1010     |
| 0x008   | DES_KEY2_L | RW   | 0x0000.0000 | DES Key 2 LSW for 128-Bit Key | 1010     |

Table 14-8. DES Register Map (continued)

| Offset  | Name          | Type | Reset       | Description                     | See page |
|---|---------------|------|-------------|---------------------------------|----------|
| 0x00C   | DES_KEY2_H    | RW   | 0x0000.0000 | DES Key 2 MSW for 128-Bit Key   | 1010     |
| 0x010   | DES_KEY1_L    | RW   | 0x0000.0000 | DES Key 1 LSW for 64-Bit Key    | 1010     |
| 0x014   | DES_KEY1_H    | RW   | 0x0000.0000 | DES Key 1 MSW for 64-Bit Key    | 1010     |
| 0x018   | DES_IV_L      | RW   | 0x0000.0000 | DES Initialization Vector       | 1011     |
| 0x01C   | DES_IV_H      | RW   | 0x0000.0000 | DES Initialization Vector       | 1012     |
| 0x020   | DES_CTRL      | RW   | 0x8000.0000 | DES Control                     | 1013     |
| 0x024   | DES_LENGTH    | RW   | 0x0000.0000 | DES Cryptographic Data Length   | 1014     |
| 0x028   | DES_DATA_L    | RW   | 0x0000.0000 | DES LSW Data RW                 | 1015     |
| 0x02C   | DES_DATA_H    | RW   | 0x0000.0000 | DES MSW Data RW                 | 1016     |

## 14.7 DES Register Description

This section lists and describes the DES registers, in numerical order by address offset.

- Register 1: DES Key 3 LSW for 192-Bit Key (DES\_KEY3\_L), offset 0x000**
- Register 2: DES Key 3 MSW for 192-Bit Key (DES\_KEY3\_H), offset 0x004**
- Register 3: DES Key 2 LSW for 128-Bit Key (DES\_KEY2\_L), offset 0x008**
- Register 4: DES Key 2 MSW for 128-Bit Key (DES\_KEY2\_H), offset 0x00C**
- Register 5: DES Key 1 LSW for 64-Bit Key (DES\_KEY1\_L), offset 0x010**
- Register 6: DES Key 1 MSW for 64-Bit Key (DES\_KEY1\_H), offset 0x014**

The function of each of these registers is described in more detail in Table 14-9 on page 1010.

**Note:** A read of this register returns all zeros.

**Table 14-9. DES Key Register Mapping**

| Register Name | Address Offset | Description                           |
|---------------|----------------|---------------------------------------|
| DES_KEY3_L    | 0x00000000     | KEY3 (LSW) for 192-bit key            |
| DES_KEY3_H    | 0x00000004     | KEY3 (MSW) for 192-bit key            |
| DES_KEY2_L    | 0x00000008     | KEY2 (LSW) for 192-bit key            |
| DES_KEY2_H    | 0x0000000C     | KEY2 (MSW) for 192-bit key            |
| DES_KEY1_L    | 0x00000010     | KEY1 (LSW) for 64-bit key/192-bit key |
| DES_KEY1_H    | 0x00000014     | KEY1 (MSW) for 64-bit key/192-bit key |

DES Key for 192-Bit Key (DES\_KEYn\_n)

Base 0x4403.8000  
 Offset 0x000  
 Type RW, reset 0x0000.0000

| Bit/Field | Name | Type | Reset      | Description |
|-----------|------|------|------------|-------------|
| 31:0      | KEY  | RW   | 0x00000000 | Key Data    |

**Register 7: DES Initialization Vector (DES\_IV\_L), offset 0x018**

Least significant word of the initialization vector.

## DES Initialization Vector (DES\_IV\_L)

Base 0x4403.8000

Offset 0x018

Type RW, reset 0x0000.0000

| Bit/Field | Name | Type | Reset      | Description                                    |
|-----------|------|------|------------|--|
| 31:0      | IV_L | RW   | 0x00000000 | Initialization vector for CBC, CFB modes (LSW) |

**Register 8: DES Initialization Vector (DES\_IV\_H), offset 0x01C**

Most significant word of the initialization vector.

DES Initialization Vector (DES\_IV\_H)

Base 0x4403.8000  
 Offset 0x01C  
 Type RW, reset 0x0000.0000

| Bit/Field | Name | Type | Reset      | Description                                    |
|-----------|------|------|------------|--|
| 31:0      | IV_H | RW   | 0x00000000 | Initialization vector for CBC, CFB modes (MSW) |

**Register 9: DES Control (DES\_CTRL), offset 0x020**

## DES Control (DES\_CTRL)

Base 0x4403.8000

Offset 0x020

Type RW, reset 0x8000.0000

|       |          |          |    |    |    |    |    |    |    |    |    |      |    |      |           |             |              |

|-----------|--------------|------|-------|---|
| 31        | CONTEXT      | R    | 1     | If 1, this read-only status bit indicates that the context data registers can be overwritten and the host is permitted to write the next context.   |
| 30:6      | reserved     | R    | 0     | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 5:4       | MODE         | RW   | 0     | Select CBC, ECB or CFB mode0x0: ECB mode0x1: CBC mode0x2: CFB mode0x3: reserved   |
| 3         | TDES         | RW   | 0     | Select DES or triple DES encryption/decryption.0x0: DES mode0x1:TDESmode  |
| 2         | DIRECTION    | RW   | 0     | Select encryption/decryption 0x0: decryption is selected0x1: Encryption is selected   |
| 1         | INPUT_READY  | R    | 0     | When 1, ready to encrypt/decrypt data   |
| 0         | OUTPUT_READY | R    | 0     | When 1, Data decrypted/encrypted ready  |

### Register 10: DES Cryptographic Data Length (DES\_LENGTH), offset 0x024

Indicates the cryptographic data length in bytes for all modes. Once processing is started with this context, this length decrements to zero. Data lengths up to (232 - 1) bytes are allowed. A write to this register triggers the engine to start using this context.

**Note:** A read of this register returns all zeros.

#### DES Cryptographic Data Length (DES\_LENGTH)

Base 0x4403.8000  
 Offset 0x024  
 Type RW, reset 0x0000.0000

| Bit/Field | Name   | Type | Reset      | Description                                      |
|-----------|--------|------|------------|--|
| 31:0      | LENGTH | RW   | 0x00000000 | Cryptographic data length in bytes for all modes |

**Register 11: DES LSW Data RW (DES\_DATA\_L), offset 0x028**

Data register (LSW) to read/write encrypted/decrypted data.

## DES LSW Data RW (DES\_DATA\_L)

**14.8 DES  $\mu$ DMA Interrupt Register Descriptions (CCM Offset)**

This section lists and describes the DES  $\mu$ DMA registers, in numerical order by address offset. Registers in this section are relative to the base address of 0x4403.0000.

### Register 19: DES DMA Interrupt Mask (DES\_DMAIM), offset 0x030

The **DES DMA Interrupt Mask** register control interrupt behavior and are used to program which interrupts are suppressed.

## 15 SHA/MD5 Accelerator

The SHA/MD5 module provides hardware-accelerated hash functions and can run:

- MD5 message digest algorithm developed by Ron Rivest in 1991
- SHA-1 algorithm compliant with the [FIPS 180-3 standard](#)
- SHA-2 (SHA-224 and SHA-256) algorithm compliant with the FIPS 180-3 standard
- Hash message authentication code (HMAC) operation

The algorithms produce a condensed representation of a message or a data file, called digest or signature, which can then be used to verify the message integrity.

- Hashing of 0 to  $2^{33} - 2$  bytes of data (of which  $2^{32} - 1$  bytes are in one pass) using the MD5, SHA-1, SHA-224, or SHA-256 hash algorithm (byte granularity only, no support for bit granularity)
- Automatic HMAC key preprocessing for HMAC keys up to 64 bytes
- Host-assisted HMAC key preprocessing for HMAC keys larger than 64 bytes
- HMAC from precomputes (inner/outer digest) for improved performance on small blocks
- Supports  $\mu$ DMA operation for data and context in/result out transfers
- Supports interrupt to read the digest (signature)

### 15.1 SHA/MD5 Functional Description

#### 15.1.1 SHA/MD5 Block Diagram

Figure 15-1 on page 1029 shows the module architecture, which consists of four primary blocks: the Hash/HMAC engine, the configuration registers and the interface to  $\mu$ DMA and the interrupt handler.

Figure 15-1. SHA/MD5 Module Block Diagram

### 15.1.1.1 Configuration Registers

The configuration registers contain the following global control and status registers for the SHA/MD5 Module:

- System control register that controls the mode of operation (**SHA\_SYSCONFIG** register)
- μDMA interrupt control registers (**SHA\_DMAIM**, **SHA\_DMARIS**, **SHA\_DMAMIS**, and **SHA\_DMAIC** registers, which reside in the Encryption Control Base address space)
- Interrupt status register (**SHA\_IRQSTATUS** register)
- Enable register (**SHA\_IRQENABLE** register)

### 15.1.1.2 Hash/HMAC Engine

The Hash/HMAC engine performs the SHA-1, SHA-2, or MD5 hash computation. When loaded with a data block, and optionally an intermediate digest, it independently performs the hash computation (64 or 80 rounds, depending on the algorithm) on that data block.

It can also start from the specified initial digest values instead of a loaded intermediate. Furthermore, it can perform the IPAD and OPAD XORs for MAC operations. The hash core does not perform any hash padding; this is performed in the Host Interface Block, where the data input registers are located. A loaded data block must always be a full 64 bytes (512 bits) long.

### 15.1.1.3 Hash Core Control

When the hash core is idle or done, a new hash operation can be started. Any additional information needed by the hash core (mode of operation, data to process, input digest if not starting from algorithm constants or continuing) must be provided by programming the SHA registers before the core can accept the operation.

#### 15.1.1.4 Host Interface Bank

The Host Interface Bank can access the hash core for hashing individual 64-byte hash blocks. The Host Interface Bank contains registers such as the data FIFO (**SHA Data n Input (SHA\_DATA\_n\_IN)** registers), the **SHA Inner Digest x (SHA\_IDIGEST\_X)** registers, and several control and status registers.

The Host Interface Block contains all relevant control logic for performing hash and HMAC computations on large (that is, larger than one hash block) blocks of data, including hash padding, final hash, and outer hash. It provides the necessary flow control to the SHA  $\mu$ DMA and interrupt interface.

#### 15.1.2 Power Management

To save power, the application can disable the clock to the SHA/MD5 module when not in use. The SHA/MD5 is clock gated by setting the `SHACFG` bit in the **Cryptographic Modules Clock Gating Request (CCMCGREQ)** register, CCM offset 0x204. The SHA in addition to the AES, DES, and Enhanced CRC can also be clock gated as a group by setting the `D0` bit in the **CRC and Cryptographic Modules Deep-Sleep Mode Clock Gating Control (DCGCCM)** register, System Control Module offset 0x874.

#### 15.1.3 Reset Management

To perform a software reset of the SHA module, write a 1 to the `SOFTRESET` bit in the **SHA System Configuration (SHA\_SYSCONFIG)** register. The `RESETDONE` bit in the **SHA System Status (SHA\_SYSSTATUS)** register indicates that the software reset is complete when its value is 1. When the software reset completes, the `SOFTRESET` bit in the **SHA\_SYSCONFIG** register is automatically reset. Software must ensure that the software reset completes before doing any operations.

The behavior of the software reset is the same as the hardware reset, except that the software reset bit resets this module without affecting the reset core domain of the entire device.

#### 15.1.4 $\mu$ DMA and Interrupt Requests

The SHA/MD5 module can operate in  $\mu$ DMA mode where the module can assert a  $\mu$ DMA request for context in, context out, or data input. The  $\mu$ DMA signals that can be generated are:

- Context In  $\mu$ DMA request (SHA/MD5 0 Cin): Request for Key, Digest, Mode and LENGTH information
- Context Out  $\mu$ DMA request (SHA/MD5 0 Cout): Request for read from HMAC
- Data In  $\mu$ DMA request (SHA/MD5 0 Din): Request input data in multiples of 16 bytes

The SHA/MD5 Module be programmed to assert an interrupt when the  $\mu$ DMA has completed its last transfer by programming the **SHA DMA Interrupt Mask (SHA\_DMAIM)**, at the CRC and Cryptographic Modules (CCM) offset 0x010. The **SHA DMA Raw Interrupt Status (SHA\_DMARIS)** register, at CCM offset 0x014, indicates when the  $\mu$ DMA has completed and can be cleared by the **SHA DMA Interrupt Clear (SHA\_DMAIC)** register at CCM offset 0x01C.

**Note:** The SHA module can only be accessed through privileged mode. If the  $\mu$ DMA is used for SHA transfers, then the  $\mu$ DMA's **DMA Channel Control (DMACHCTL)** register also needs to be programmed to allow for privileged accesses.

If context and data transfers are to be handled through software in Interrupt Mode, then the **SHA Interrupt Enable (SHA\_IRQENABLE)**, offset 0x11C, can be used to enable interrupt triggering

when context out, context in, data in or data out is ready. The **SHA Interrupt Status (SHA\_IRQSTATUS)**, offset 0x118, indicates when an interrupt is triggered.

**Note:** If the application uses Interrupt Mode, an interrupt is generated for each block of processed data. To support larger data flow, SHA  $\mu$ DMA Mode should be used and the bits in the **SHA\_IRQENABLE** register should be cleared.

**Table 15-1. Interrupts and Events**

| Event                         | Description              |
|-------------------------------|--------------------------|
| SHA_IRQSTATUS[3]: CONTEXT_OUT | Context output interrupt |
| SHA_IRQSTATUS[1]: DATA_IN     | Data input interrupt     |
| SHA_IRQSTATUS[0]: CONTEXT_IN  | Context input interrupt  |

### 15.1.5 Operation Description

The SHA/MD5 Module can run the SHA-1, SHA-224, SHA-256, and MD5 algorithms, depending on the value of the **ALGO** bit field in the **SHA Mode (SHA\_MODE)** register, offset 0x044, as listed in Table 15-2 on page 1031.

**Table 15-2. SHA/MD5 Module Algorithm Selection**

| ALGO Field Value in SHA_MODE Register | Description                |
|---------------------------------------|----------------------------|
| 0x0                                   | MD5 algorithm selected     |
| 0x1                                   | SHA-1 algorithm selected   |
| 0x2                                   | SHA-224 algorithm selected |
| 0x3                                   | SHA-256 algorithm selected |

#### 15.1.5.1 SHA Mode

##### **Starting a New Hash**

To start a new hash, follow these steps:

1. Set the **ALGO** bitfield in the **SHA\_MODE** register, at offset 0x044, to 0x1, 0x2, or 0x3 to select SHA-1, SHA-224, or SHA-256, respectively.
2. Set the **ALGO\_CONSTANT** bit in the **SHA\_MODE** register to 1 to initialize all **SHA Inner/Outer Digest n** registers from **SHA\_ODIGEST\_A/SHA\_IDIGEST\_A** to **SHA\_ODIGEST\_H/SHA\_IDIGEST\_H** with their default values specified by the algorithm, and set the **SHA\_DIGESTCOUNT** register to 0.
3. Set the **CLOSE\_HASH** bit of the **SHA Mode (SHA\_MODE)** register to let the SHA engine do the padding. If the Hash is computed in one shot, the length of the message can be any value up to 128 MB. To process an intermediate Hash digest, the **CLOSE\_HASH** bit is set to 0, in which case the packets hashed must be 64 bytes; the last packet must be hashed with the **CLOSE\_HASH** bit set to 1.
4. Specify the **LENGTH** field in the **SHA Length (SHA\_LENGTH)** register of the hash data to process in bytes.

After the configuration is complete, the **INPUT\_READY** status bit equals 1 in the **SHA Interrupt Status (SHA\_IRQSTATUS)** register (regardless of whether or not the **M\_INPUT\_READY** bit in the **SHA\_IRQENABLE** register is set. When this bit is set, it indicates the SHA engine can receive the

data to process. Data must be written to the 16 x 32-bit **SHA\_DATA\_n\_IN** registers that provide storage for one 64-byte block of data. Unless the `CLOSE_HASH` bit is set, all of the **SHA\_DATA\_n\_IN** input buffers must be filled. Data can be written by single write accesses to the 16 registers from a processor or by a DMA transfer.

For  $\mu$ DMA transfers, the `DMA_EN` bit must be set in the **SHA\_SYSCONFIG** register and the appropriate mask bits must be set in the **SHA\_DMAIM** register before starting the new hash. Note that if the  $\mu$ DMA is used for transfers, the **SHA\_IRQENABLE** register should be clear so all interrupts are generated through the  $\mu$ DMA interrupt registers.

The  $\mu$ DMA must be configured to transfer 16 data words of 32 bits each time it is triggered by a  $\mu$ DMA request from the SHA/MD5 Module. The 16 data words written are sent to the 16 **SHA\_DATA\_n\_IN** registers.

The module detects that a 64-byte block is available, and then moves the data to a working register space for processing and asserts the `INPUT_READY` bit in the **SHA\_IRQSTATUS** register to 1. If the `DMA_EN` bit in the **SHA\_SYSCONFIG** register has been set to 1, a new  $\mu$ DMA request triggers a new block transfer; otherwise, the processor polls the `INPUT_READY` bit and writes the 16 data words of 32 bits when it equals 1.

This operation is repeated until the length of the message to hash is reached. The `OUTPUT_READY` bit in the **SHA\_IRQSTATUS** register then indicates that the hash operation is complete. If the `IT_EN` bit in the **SHA\_SYSCONFIG** register is set, an interrupt (active low) is also generated to indicate the hash completion.

The processor can then read the eight digest registers A through H that contain the hash and/or HMAC result. If the hash is an intermediate result of a larger hash, the digest count register must also be read and saved.

**Note:** The number of digest registers used depends on the algorithm selected for the SHA/MD5 Module (MD5, SHA-1, SHA-224, or SHA-256), as shown in Table 15-3 on page 1032 and Table 15-4 on page 1033

**Table 15-3. Outer Digest Registers**

| Register      | Address | MD5<br>(Read/Write)      | SHA-1<br>(Read/Write)     | SHA-2 (Read/Write)     | HMAC Key<br>Processing (write) |
|---------------|---------|--------------------------|---------------------------|------------------------|--------------------------------|
| SHA_ODIGEST_A | 0x000   | Outer digest<br>[127:96] | Outer digest<br>[159:128] | Outer digest [255:224] | HMAC Key [31:0]                |
| SHA_ODIGEST_B | 0x004   | Outer digest<br>[95:64]  | Outer digest<br>[127:96]  | Outer digest [223:192] | HMAC key [63:32]               |
| SHA_ODIGEST_C | 0x008   | Outer digest<br>[63:32]  | Outer digest<br>[95:64]   | Outer digest [191:160] | HMAC key [95:64]               |
| SHA_ODIGEST_D | 0x00C   | Outer digest<br>[31:0]   | Outer digest<br>[63:32]   | Outer digest [159:128] | HMAC key [127:96]              |
| SHA_ODIGEST_E | 0x010   |                          | Outer digest [31:0]       | Outer digest [127:96]  | HMAC key [159:128]             |
| SHA_ODIGEST_F | 0x014   |                          |                           | Outer digest [95:64]   | HMAC key [191:160]             |
| SHA_ODIGEST_G | 0x018   |                          |                           | Outer digest [63:32]   | HMAC key [223:192]             |
| SHA_ODIGEST_H | 0x01C   |                          |                           | Outer digest [31:0]    | HMAC key [255:224]             |

**Table 15-4. Inner Digest Registers**

| Register      | Address | MD5<br>(Read/Write)      | SHA-1<br>(Read/Write)     | SHA-2<br>(Read/Write)     | SHA-256<br>(Read/Write)   | HMAC Key<br>Processing (write) |
|---------------|---------|--------------------------|---------------------------|---------------------------|---------------------------|--------------------------------|
| SHA_IDIGEST_A | 0x020   | Inner digest<br>[127:96] | Inner digest<br>[159:128] | Inner digest<br>[223:192] | Inner digest<br>[255:224] | HMAC key<br>[287:256]          |
| SHA_IDIGEST_B | 0x024   | Inner digest<br>[95:64]  | Inner digest<br>[127:96]  | Inner digest<br>[191:160] | Inner digest<br>[223:192] | HMAC key<br>[319:288]          |
| SHA_IDIGEST_C | 0x028   | Inner digest<br>[63:32]  | Inner digest<br>[95:64]   | Inner digest<br>[159:128] | Inner digest<br>[191:160] | HMAC key<br>[351:320]          |
| SHA_IDIGEST_D | 0x02C   | Inner digest<br>[31:0]   | Inner digest<br>[63:32]   | Inner digest<br>[127:96]  | Inner digest<br>[159:128] | HMAC key<br>[383:352]          |
| SHA_IDIGEST_E | 0x030   |                          | Inner<br>digest[31:0]     | Inner digest<br>[95:64]   | Inner digest<br>[127:96]  | HMAC key<br>[415:384]          |
| SHA_IDIGEST_F | 0x034   |                          |                           | Inner digest<br>[63:32]   | Inner digest [95:64]      | HMAC key<br>[447:416]          |
| SHA_IDIGEST_G | 0x038   |                          |                           | Inner digest [31:0]       | Inner digest [63:32]      | HMAC key<br>[479:448]          |
| SHA_IDIGEST_H | 0x03C   |                          |                           |                           | Inner digest[31:0]        | HMAC key<br>[511:480]          |

**Note:** Inner digests are initial, intermediate, and result digests.

#### **Outer Digest Registers**

The **SHA\_ODIGEST\_A** to **SHA\_ODIGEST\_H** registers are relevant only for HMAC operations; the contents are ignored for hash operations.

Before writing to the digest registers, the operation must be configured in the **SHA Mode (SHA\_MODE)** register. For HMAC operations without key processing, the **HMAC\_KEY\_PROC** bit must be clear in the **SHA\_MODE** register before starting operations. Once the algorithm has been programmed in the **SHA\_MODE** register, only the relevant digest registers for the selected algorithm must be written:

- **SHA\_ODIGEST\_A** to **SHA\_ODIGEST\_D** registers for MD5
- **SHA\_ODIGEST\_A** to **SHA\_ODIGEST\_E** registers for SHA-1
- **SHA\_ODIGEST\_A** to **SHA\_ODIGEST\_H** registers for SHA-2 (224 to 256)

When HMAC key processing is enabled (**HMAC\_KEY\_PROC**=1), these registers must be written with the lower 256 bits of the HMAC key to be processed in little-endian format (first byte of key string in bits [7:0]).

**Note:** If the HMAC key is less than 512 bits, it must be properly padded with zeros: all 16 HMAC key registers must be written explicitly; the core does not pad. Additionally, if the HMAC key is larger than 512 bits, the host must perform a preprocessing step to reduce it to one 512-bit block. This involves hashing the large key and padding the hash result with zeros until it is 512 bits wide.

The computed outer digest can be read from these registers when the **SHA Interrupt Status (SHA\_IRQSTATUS)** register when the **OUTPUT\_READY** bit has been set indicating that the operation is done.

**Note:** If no HMAC key processing is performed, the value read is identical to the value written initially. The MD5 outer digest is available from registers **SHA\_ODIGEST\_A** to

**SHA\_ODIGEST\_D**, the SHA-1 outer digest from registers **SHA\_ODIGEST\_A** to **SHA\_ODIGEST\_E**, and the SHA-224 and SHA-256 outer digest from registers **SHA\_ODIGEST\_A** to **SHA\_ODIGEST\_H**.

**Note:** The HMAC key is not preserved. If another block must be authenticated using the same key, the key must be reloaded by the host. If the same key must be used many times, it is advisable to do a HMAC key processing-only pass to obtain the inner and outer digest precomputes and load these precomputes for subsequent passes (only the inner digest must be reloaded if the outer digest is not modified by the host), because this saves two hash blocks worth of computation time.

### **Inner Digest Registers**

The **SHA\_IDIGEST\_A** to **SHA\_IDIGEST\_H** registers are used for HMAC and hash operations.

The inner/initial digest for HMAC and hash continue operations (**HMAC\_KEY\_PROC** = 0 and **ALGO\_CONSTANT** = 0) must be written to these registers before starting the operation by writing to the **SHA\_MODE** register. Only the relevant digest registers for the selected algorithm must be written:

- **SHA\_IDIGEST\_A** to **SHA\_IDIGEST\_D** registers for MD5
- **SHA\_IDIGEST\_A** to **SHA\_IDIGEST\_E** registers for SHA-1
- **SHA\_IDIGEST\_A** to **SHA\_IDIGEST\_H** registers for SHA-2

When **ALGO\_CONSTANT** = 1 in the **SHA\_MODE** register, the **SHA Inner Digest n (SHA\_IDIGEST\_n)** registers do not need to be written by the application because they are overwritten with the appropriate algorithm constants.

When **HMAC\_KEY\_PROC** is 1, these registers must be written with the upper 256 bits of the HMAC key to be processed in little-endian format (first byte of key string in bits [7:0]).

**Note:** If the HMAC key is less than 512 bits, it must be properly padded with zeros: all 16 HMAC key registers must be written explicitly; the core does not pad. Additionally, if the HMAC key is larger than 512 bits, the host must perform a preprocessing step to reduce it to one 512-bit block. This involves hashing the large key and padding the hash result with zeros until it is 512 bits wide.

The order of the bytes within the digest is such that it can be fed back unmodified into the little-endian data input when preprocessing HMAC keys larger than 64 bytes, or it can typically be inserted unmodified into a little-endian data stream (for example, IPSEC packets), regardless of the selected algorithm.

**Note:** The HMAC key or inner digest is not preserved. If another block must be authenticated using the same key, the key or inner digest must be reloaded by the host. If the same key must be used many times, it is advisable to do a HMAC key processing-only pass to obtain the inner and outer digest precomputes and load these precomputes for subsequent passes (only the inner digest must be reloaded if the outer digest is not modified by the host), because this saves two hash blocks worth of computation time.

### **Closing a Hash**

The amount of data to hash is not necessarily a multiple of 64 bytes. The **CLOSE\_HASH** bit in the **SHA\_MODE** register is set to append padding so that the message size becomes a multiple of 64 bytes. Consequently, a minimum of 9 bytes must be added to the message. Nine bytes is the minimum number of bytes that contains the minimum 65-bit padding specified by FIPS 180-1.

If the size of the last block of data is less than or equal to 55 bytes, no additional 64-byte block is required. However, if the last block of data contains more than 55 bytes, an extra 64-byte block must be added to make the padding as specified by FIPS 180-1. This extra block is added automatically by the hardware; thus, the module is fed with a 64-byte block of data. However, appending a pad on the last block of data can result in the creation of an extra 64-byte block.

The one or two last blocks that contain the padding are processed in the same way as the other blocks. Hash completion is then indicated in the same way as for a new hash, and the hash result can be read in the digest registers. The **SHA\_DIGESTCOUNT** register returns restored Digest Count + Length when it is read, and hashing completes.

Assuming a message of 129 bytes, Table 15-5 on page 1035 shows the SHA digest for three passes. Table 15-6 on page 1035 shows the SHA digest for one pass.

**Table 15-5. SHA Digest Processed in Three Passes**

|             | Digest (A to E)            | SHA_DIGESTCOUNT | SHA_MODE and SHA_LENGTH  | SHA_DATA_n_IN              |
|-------------|----------------------------|-----------------|--|----------------------------|
| First pass  |                            |                 | WRITE:<br>LENGTH=64<br>ALGO (dependent on the algorithm to apply)<br>ALGO_CONSTANT=1<br>CLOSE_HASH=0 | First 64 bytes of message  |
| Second pass | Round 1 digest calculation | WRITE: 64       | WRITE:<br>LENGTH=64<br>ALGO (dependent on the algorithm to apply)<br>ALGO_CONSTANT=0<br>CLOSE_HASH=0 | Second 64 bytes of message |
| Third pass  | Round 2 digest calculation | WRITE: 128      | Write:<br>LENGTH=1<br>ALGO (dependent on the algorithm to apply)<br>ALGO_CONSTANT=0<br>CLOSE_HASH=1  | Last byte of message       |
|             | Final digest               | READ: 129       |  |                            |

If the three passes are not performed in succession, the digest registers must be saved and restored for the next use of the SHA/MD5 engine. If the rounds are performed consecutively, there is no need to do anything with the digest registers.

**Table 15-6. SHA Digest Processed in One Pass**

|            | Digest (A to E) | SHA_DIGEST_COUNT | SHA_MODE and SHA_LENGTH   | SHA_DATA_n_IN             |
|------------|-----------------|------------------|---|---------------------------|
| First pass |                 |                  | WRITE:<br>LENGTH=129<br>ALGO (dependent on the algorithm to apply)<br>ALGO_CONSTANT=1<br>CLOSE_HASH=1 | First 64 bytes of message |

Table 15-6. SHA Digest Processed in One Pass (continued)

|  | Digest (A to E)            | SHA_DIGEST_COUNT | SHA_MODE and SHA_LENGTH | SHA_DATA_n_IN              |
|--|----------------------------|------------------|-------------------------|----------------------------|
|  | Round 1 digest calculation |                  |                         | Second 64 bytes of message |
|  | Round 2 digest calculation |                  |                         | Last byte of message       |
|  | Final digest               | Read: 129        |                         |                            |

### 15.1.5.2 MD5 Mode

#### Starting a New Hash

To start a new hash, perform the following steps:

1. Set the **ALGO** bit field in the **SHA\_MODE** register to 0x0 to select the MD5 algorithm.
2. Set the **ALGO\_CONSTANT** bit to 1 in the **SHA\_MODE** register to initialize all digest registers from **SHA\_ODIGEST\_A/SHA\_IDIGEST\_A** to **SHA\_ODIGEST\_H/SHA\_IDIGEST\_H** with default values specified by the algorithm, and set the **SHA\_DIGESTCOUNT** register to 0.
3. Specify the **LENGTH** field in the **SHA\_LENGTH** register of the hash data to process in bytes.
4. Set the **CLOSE\_HASH** bit in the **SHA\_MODE** register to let the SHA/MD5 engine do the padding. If MD5 is computed in one shot, the length of the message can be any value up to . To process an intermediate MD5 digest, the **CLOSE\_HASH** bit is set to 0, in which case packets to be hashed must be 64 bytes; the last packet must be hashed with the **CLOSE\_HASH** bit set to 1.

After the configuration is complete, the hash engine can receive the data to process (the **INPUT\_READY** bit is 1 in the **SHA\_IRQSTATUS** register). Data must be written to the 16 x 32-bit **SHA\_DATA\_n\_IN** registers that provide storage for one 64-byte block of data. Unless the **CLOSE\_HASH** bit is set in the **SHA\_MODE** register, the **SHA\_DATA\_n\_IN** 64-byte input buffer must be filled. Data can be written by single write transactions to the 16 registers from a processor or by a  $\mu$ DMA transfer.

For a  $\mu$ DMA transfer, the **SDAM\_EN** bit must be set in the **SHA\_SYSCONFIG** register before starting the new hash and the  $\mu$ DMA channel for SHA/MD5 0 Data In Request must be configured. The  $\mu$ DMA must be configured to the appropriate hash transfer size. See “Micro Direct Memory Access ( $\mu$ DMA)” on page 667 for more information on programming the  $\mu$ DMA. A  $\mu$ DMA done is asserted after the last **SHA\_DATA\_n\_IN** register is filled..

The module detects that a 64-byte block is available, and then moves the data to a working register space for processing and sets the **INPUT\_READY** bit to 1 in the **SHA\_IRQSTATUS** register. If the **DMA\_EN** bit is set in the **SHA\_SYSCONFIG** register, then a new  $\mu$ DMA request triggers a new block transfer; otherwise, the processor polls the **INPUT\_READY** bit in the **SHA\_IRQSTATUS** register and writes the 16 data words of 32 bits when it equals 1.

This operation repeats until the length of the message to hash is reached. The **OUTPUT\_READY** bit in the **SHA\_IRQSTATUS** register then indicates that the hash operation is complete. If the **IT\_EN** bit in the **SHA\_SYSCONFIG** register is set, an interrupt (active low) is also generated to indicate the hash completion.

### Closing a Hash

The amount of data to hash is not necessarily a multiple of 64 bytes. In this case, the CLOSE\_HASH bit in the SHA\_MODE register must be set to append padding so that the message size becomes a multiple of 64 bytes. See the previous MD5 algorithm for more information on padding.

The module is fed with a 64-byte block of data, as long as enough data is available. However, a pad is appended on the last block of data. This can result in the creation of an extra 64-byte block.

The one or two last blocks that contain the padding are processed the same way as the other blocks. Hash completion is then indicated the same way as for a new hash, and the 128-bit result can be read in the digest registers. The **SHA\_DIGESTCOUNT** register returns restored digest count and length when it is read, and hashing completes.

#### 15.1.5.3 Generating an Software Interrupt

If the **IT\_EN** bit is 1 in the **SHA\_SYSCONFIG** register, an interrupt is generated at the completion of the hash by the following steps:

1. Receive last block of data (= 64 bytes). (The number of data bytes defined by the **SHA\_LENGTH** register is received in the digest registers, from **SHA\_ODIGEST\_A/SHA\_IDIGEST\_A** to **SHA\_ODIGEST\_H/SHA\_IDIGEST\_H**.)
2. If required, apply padding to the last block of data.
3. Hash the last block of data (80 cycles in SHA-1 mode and 64 cycles in MD5, SHA-224, and SHA-256 modes).
4. If required, add an extra 64-byte block of data to complete the padding.
5. Hash this extra block of data (80 cycles in SHA-1 mode and 64 cycles in MD5, SHA-224, and SHA-256 modes).
6. An interrupt is generated (active low).

#### 15.1.6 SHA/MD5 Performance Information

The following table lists the performance for all supported key sizes and modes of operations. It assumed that the engine is kept fully utilized (that is, the host is supplying input block and retrieving output blocks in such a way, that the engine never has to wait for input) and that the previous output has been retrieved before the next output is ready.

Maximum throughput does not include per operation overhead cycles, as the impact on the throughput depends on the size of the block being processed, and would be negligible for large blocks anyway.

**Table 15-7. SHA/MD5 Performance**

| Operation | Algorithm | Cycles per operation | Cycles per block |
|-----------|-----------|----------------------|------------------|
| Hash      | MD5       | 0 / 65               | 65               |
|           | SHA-1     | 0 / 81               | 81               |
|           | SHA-224   | 0 / 65               | 65               |
|           | SHA-256   | 0 / 65               | 65               |

Table 15-7. SHA/MD5 Performance (continued)

| Operation             | Algorithm | Cycles per operation | Cycles per block |
|-----------------------|-----------|----------------------|------------------|
| HMAC from Key         | MD5       | 196 / 261            | 65               |
|                       | SHA-1     | 244 / 325            | 81               |
|                       | SHA-224   | 196 / 261            | 65               |
|                       | SHA-256   | 196 / 261            | 65               |
|                       | MD5       | 66 / 131             | 65               |
| HMAC from precomputes | SHA-1     | 82 / 163             | 81               |
|                       | SHA-224   | 66 / 131             | 65               |
|                       | SHA-256   | 66 / 131             | 65               |

**Note:** An extra block needs to be processed if the length of the data block to be hashed module 64 is 0 or equal to 56.

## 15.1.7 SHA/MD5 Programming Guide

This section covers the hardware programming sequences for configuration and use of the SHA/MD5 Module.

### 15.1.7.1 Global Initialization

#### *Surrounding Modules Global Initialization*

This section identifies the requirements for initializing the surrounding modules when the SHAM is used for the first time after a device reset.

1. When reset has completed, enable the SHA/MD5 Module by setting the `R0` bit in the **CRC And Cryptographic Modules Run Mode Clock Gating Control (RCGCCM)** register, System Control offset 0x674. When the `R0` bit is set in the **CRC and Cryptographic Modules (PRCCM)** register, System Control offset 0xA74 register, the SHA/MD5 Module is powered and ready to be configured.
2. Configure the SHA  $\mu$ DMA channels for Context In, Context Out, Data In, and/or Data Out by programming the appropriate encoding value in the **DMA Channel Map Select n (DMACHMAPn)** register in the  $\mu$ DMA module, offset 0x510. For more information on how to program channel assignments as well as enabling burst and the configured channels, refer to “Micro Direct Memory Access ( $\mu$ DMA)” on page 667.
3. Execute a software reset by setting the `SOFTRESET` bit in the **SHA\_SYSCONFIG** register. When reset is complete, the `RESETDONE` bit reads as 1 in the **SHA\_SYSSTATUS** register.
4. If the SHA channels are configured in the  $\mu$ DMA, enable the required SHA DMA requests by programming bits [9:5] of the **SHA\_SYSCONFIG** register, in addition to the completion interrupts in the **SHA DMA Interrupt Mask (SHA\_DMAIM)** register, CRC and Cryptographic Modules offset 0x020.

#### *Starting a New HMAC using the SHA-1 Hash Function and HMAC Key Processing*

The following procedure is used to begin a new HMAC operation, starting from initial digest values.

1. Load the key value in the **SHA\_ODIGEST\_A/SHA\_IDIGEST\_A** to **SHA\_ODIGEST\_H/SHA\_IDIGEST\_H** registers.

2. Pad the rest of the SHA\_ODIGEST\_x and SHA\_IDIGEST registers with zeros.
3. Load the message in the **SHA\_DATA\_n\_IN** FIFO registers.
4. Enable HMAC key processing by setting the HMAC\_KEY\_PROC bit in the **SHA\_MODE** register.
5. Select the SHA-1 hash function by programming the ALGO bit in the **SHA\_MODE** register to 0x1.
6. Select the already loaded key by programming the ALGO\_CONSTANT bit in the SHA\_MODE register to 0x0.
7. Set the CLOSE\_HASH bit and the HMAC\_OUTER\_HASH bit in the **SHA\_MODE** register so that appropriate padding is inserted and the outer hash is performed immediately after the inner hash has finished.
8. Program the **SHA\_LENGTH** register with the block length. Writing this register triggers the HMAC engine to begin processing.

**Note:** If more than one pass is used during the process (SHA\_MODE[4] CLOSE\_HASH == 0x0), the block length value must be a 64-byte multiple. From this point, three operational modes are possible to continue with the processing: polling, interrupt, and DMA. For more information, see the Operational Modes Configuration section.

#### ***Subsequence - Continuing a Prior HMAC Using the SHA-1 Hash Function***

The procedure in continues a prior HMAC calculation interrupted from a high priority task.

**Table 15-8. Continuing a Prior HMAC**

| Step   | Register/Bit Field/Programming Model | Value |
|--|--------------------------------------|-------|
| Load the initial digest for the used hash algorithm.                                   | SHA_IDIGEST_i[31:0] DATA             | -     |
| Restore the digest counter with the value before the switch to the high-priority task. | SHA_DIGEST_COUNT[31:0] COUNT         | -     |
| Use the already loaded in the engine key.  | SHA_MODE[5] HMAC_KEY_PROC            | 0x0   |
| Do not use the constants of the selected hash algorithm.                               | SHA_MODE[3] ALGO_CONSTANT            | 0x0   |
| Select the SHA-1 hash algorithm.   | SHA_MODE[2:1] ALGO                   | 0x1   |
| IF: This is the last 64-byte data block from the input message?                        | User decision                        |       |
| Close the hash; an appropriate padding is added.                                       | SHA_MODE[4] CLOSE_HASH               | 0x1   |
| ENDIF  |                                      |       |
| Load the block length; this is the trigger to start processing.                        | SHA_LENGTH[31:0] LENGTH              | -     |

**Note:** This initial digest is the intermediate digest from the previous calculation before switching to the high priority task. The value is equal to context1 in .

**Note:** The value is equal to context2 in .

**Note:** The block length is equal to the context3 value in .

#### ***Subsequence - Hashing a Key Bigger than 512 Bits with the SHA-1 Hash Function***

The procedure in creates a hash value from the key in only one pass.

**Table 15-9. SHA-1 Apply on the Key**

| Step   | Register/Bit Field/Programming Model | Value |
|--|--------------------------------------|-------|
| Load the first part of the key. (Here, the key is like a message.) | SHA_DATA_n_IN (i = 0 to 15)          | -     |
| Select the SHA-1 hash function.                                    | SHA_MODE[2:1] ALGO                   | 0x1   |
| Select a new hash operation.                                       | SHA_MODE[3] ALGO_CONSTANT            | 0x1   |
| Close the hash; the key is processed in single pass.               | SHA_MODE[4] CLOSE_HASH               | 0x1   |

### Operational Modes Configuration

#### SHA/MD5 Polling Mode

Figure 15-2 on page 1040 shows the SHA/MD5 polling mode. SHA/MD5 polling mode uses the following registers: SHA\_IRQSTATUS, SHA\_DATA\_n\_IN, SHA\_ODIGEST\_A, SHA\_DIGEST\_COUNT, and SHA\_LENGTH.

**Figure 15-2. SHA/MD5 Polling Mode**

#### SHA/MD5 Interrupt Mode

The procedure in configures the SHA/MD5 module to work in interrupt-based mode. (For the interrupt subroutine, see the Interrupt Servicing section.)

**Table 15-10. Interrupt Mode**

| Step  | Register/Bit Field/Programming Model | Value |
|---|--------------------------------------|-------|
| Enable the interrupt request to the Cortex-A8 MPU INTC. | SHA_SYSCONFIG[2] IT_EN               | 0x1   |

**Table 15-10. Interrupt Mode (continued)**

| Step  | Register/Bit Field/Programming Model | Value |
|---|--------------------------------------|-------|
| Load the message length; this is the trigger to start processing. | SHA_LENGTH[31:0] LENGTH              | -     |

**SHA/MD5 DMA Mode**

The procedure in configures the SHA/MD5 module to work in DMA-based mode.

**Table 15-11. DMA Mode**

| Step  | Register/Bit Field/Programming Model | Value |
|---|--------------------------------------|-------|
| Enable the DMA request to the CDMA controller.                    | SHA_SYSCONFIG[3] DMA_EN              | 0x1   |
| Load the message length; this is the trigger to start processing. | SHA_LENGTH[31:0] LENGTH              | -     |

**SHA/MD5 Event Servicing****Interrupt Servicing**

This section describes the interrupt event servicing of the module. Figure 15-3 on page 1042 shows the interrupt subroutine. The following registers are used in the SHA/MD5 interrupt routine: SHA\_IRQSTATUS, SHA\_DATA\_n\_IN, SHA\_ODIGEST\_A, SHA\_DIGEST\_COUNT, SHA\_LENGTH, and SHA\_IDIGEST\_A.

Figure 15-3. SHA/MD5 Interrupt Subroutine

## 15.2 SHA/MD5 Register Map

Table 15-12 on page 1042 lists the SHA/MD5 registers. The SHA Module comprises registers that exist at an offset relative to the SHA/MD5 Module base address and a small set of SHA/MD5  $\mu$ DMA interrupt registers that exist at an offset relative to an CRC and Cryptographic Modules base address. The SHA/MD5 Module register offsets are relative to the base address 0x4403.4000. The SHA  $\mu$ DMA offsets are relative to the base address 0x4403.0000 .

Table 15-12. SHA/MD5 Register Map

| Offset  | Name          | Type | Reset       | Description        | See page |
|---|---------------|------|-------------|--------------------|----------|
| <b>SHA/MD5 Module Registers (SHA/MD5 Module Offset)</b> |               |      |             |                    |          |
| 0x000   | SHA_ODIGEST_A | RW   | 0x0000.0000 | SHA Outer Digest A | 1046     |
| 0x004   | SHA_ODIGEST_B | RW   | 0x0000.0000 | SHA Outer Digest B | 1046     |
| 0x008   | SHA_ODIGEST_C | RW   | 0x0000.0000 | SHA Outer Digest C | 1046     |
| 0x00C   | SHA_ODIGEST_D | RW   | 0x0000.0000 | SHA Outer Digest D | 1046     |

Table 15-12. SHA/MD5 Register Map (continued)

| Offset | Name             | Type | Reset       | Description        | See page |
|--------|------------------|------|-------------|--------------------|----------|
| 0x010  | SHA_ODIGEST_E    | RW   | 0x0000.0000 | SHA Outer Digest E | 1046     |
| 0x014  | SHA_ODIGEST_F    | RW   | 0x0000.0000 | SHA Outer Digest F | 1046     |
| 0x018  | SHA_ODIGEST_G    | RW   | 0x0000.0000 | SHA Outer Digest G | 1046     |
| 0x01C  | SHA_ODIGEST_H    | RW   | 0x0000.0000 | SHA Outer Digest H | 1046     |
| 0x020  | SHA_IDIGEST_A    | RW   | 0x0000.0000 | SHA Inner Digest A | 1046     |
| 0x024  | SHA_IDIGEST_B    | RW   | 0x0000.0000 | SHA Inner Digest B | 1046     |
| 0x028  | SHA_IDIGEST_C    | RW   | 0x0000.0000 | SHA Inner Digest C | 1046     |
| 0x02C  | SHA_IDIGEST_D    | RW   | 0x0000.0000 | SHA Inner Digest D | 1046     |
| 0x030  | SHA_IDIGEST_E    | RW   | 0x0000.0000 | SHA Inner Digest E | 1046     |
| 0x034  | SHA_IDIGEST_F    | RW   | 0x0000.0000 | SHA Inner Digest F | 1046     |
| 0x038  | SHA_IDIGEST_G    | RW   | 0x0000.0000 | SHA Inner Digest G | 1046     |
| 0x03C  | SHA_IDIGEST_H    | RW   | 0x0000.0000 | SHA Inner Digest H | 1046     |
| 0x040  | SHA_DIGEST_COUNT | RW   | 0x0000.0000 | SHA Digest Count   | 1047     |
| 0x044  | SHA_MODE         | RW   | 0x0000.0000 | SHA Mode           | 1048     |
| 0x048  | SHA_LENGTH       | RW   | 0x0000.0000 | SHA Length         | 1050     |
| 0x080  | SHA_DATA_0_IN    | RW   | 0x0000.0000 | SHA Data 0 Input   | 1051     |
| 0x084  | SHA_DATA_1_IN    | RW   | 0x0000.0000 | SHA Data 1 Input   | 1051     |
| 0x088  | SHA_DATA_2_IN    | RW   | 0x0000.0000 | SHA Data 2 Input   | 1051     |

### 15.3 SHA/MD5 Register Descriptions

This section describes the SHA/MD5 registers.

**Note:** The SHA/MD5 registers are limited to 32-bit data accesses; 8- and 16-bit accesses are not allowed and can corrupt register contents.

The first 16 registers of HIB1 are the outer and inner digest registers.

Table 15-13. SHA/MD5 Inner/Outer Digest/HMAC Key Register Mapping

| Register Name | Address Offset | MD5 (read/write)      | SHA-1 (read/write)     | SHA-2 (read/write)     |                        | HMAC key proc (write) |
|---------------|----------------|-----------------------|------------------------|------------------------|------------------------|-----------------------|
| SHA_ODIGEST_A | 0x00000000     | Outer digest [127:96] | Outer digest [159:128] | Outer digest [255:224] |                        | HMAC key [31,0]       |
| SHA_ODIGEST_B | 0x00000004     | Outer digest [95:64]  | Outer digest [127:96]  | Outer digest [223:192] |                        | HMAC key [63,32]      |
| SHA_ODIGEST_C | 0x00000008     | Outer digest [63:32]  | Outer digest [95:64]   | Outer digest [191:160] |                        | HMAC key [95,64]      |
| SHA_ODIGEST_D | 0x0000000C     | Outer digest [31:0]   | Outer digest [63:32]   | Outer digest [159:128] |                        | HMAC key [127,96]     |
| SHA_ODIGEST_E | 0x00000010     |                       | Outer digest [31:0]    | Outer digest [127:96]  |                        | HMAC key [159,128]    |

| 31:0      | DATA | RW   | 0x0000.0000 | Digest/Key Data |

**Register 17: SHA Digest Count (SHA\_DIGEST\_COUNT), offset 0x040**

This register is written with the initial digest count and can be read to determine the digest count result. Note that for Initial Digest Count writes, bits 5:0 must be zero. This register is written the initial digest byte count when both the `HMAC_KEY_PROC` bit and the `ALGO_CONSTANT` bit is zero in the `SHA_MODE` register. When either the `HMAC_KEY_PROC` bit or the `ALGO_CONSTANT` bit is 1, this register does not need to be written because it is overwritten with 64 or 0 automatically. When starting an HMAC operation from precomputes (`HMAC_KEY_PROC=0`), the value 64 must be written in the `SHA_DIGESTCOUNT` register. Note that the value written should always be a 64 byte multiple, the lower 6 bits written are ignored. The updated digest byte count (initial digest byte count + bytes processed) can be read from this register when the status register indicates that the operation is done or when a  $\mu$ DMA context out is requested.

**Register 19: SHA Length (SHA\_LENGTH), offset 0x048**

WRITE: Block Length/Remaining Byte Count (bytes) READ: Remaining Byte Count. The value programmed MUST be a 64-byte multiple if Close Hash is set to 0. This register is also the trigger to start processing: once this register is written, the core will commence requesting input data via DMA or IRQ (if programmed length > 0) and start processing. The remaining byte count for the active operation can be read from this register when the interrupt status register indicates that the operation is suspended due to a context switch request.

## SHA Length (SHA\_LENGTH)

Base 0x4403.4000

## 15.4 SHA/MD5 $\mu$ DMA Control Register Descriptions (Encryption Control Offset)

This section lists and describes the SHA/MD5  $\mu$ DMA registers, in numerical order by address offset. Registers in this section are relative to the Encryption Control base address of 0x4403.0000.

**Note:** The SHA module can only be accessed through privileged mode. If the  $\mu$ DMA is used for SHA transfers, then the  $\mu$ DMA's **DMA Channel Control (DMACHCTL)** register also needs to be programmed to allow for privileged accesses.

**Note:** If the application uses SHA  $\mu$ DMA interrupt triggers, the bits in the **SHA\_IRQENABLE** register should be cleared.

**Register 41: SHA DMA Interrupt Mask (SHA\_DMAIM), offset 0x010**

The **SHA DMA Interrupt Mask (SHA\_DMA\_IM)** register controls interrupt behavior and are used to program which interrupts are suppressed.

**Register 44: SHA DMA Interrupt Clear (SHA\_DMAIC), offset 0x01C**

The **SHA DMA Interrupt Clear** register is used to clear the **SHA\_DMA\_RIS** and **SHA\_DMA\_MIS** registers by writing a 1 to each register bit.

**Note:** This registers always reads as zero.

## 16 General-Purpose Timers

Programmable timers can be used to count or time external events that drive the Timer input pins. The TM4C129CNCZAD General-Purpose Timer Module (GPTM) contains 16/32-bit GPTM blocks. Each 16/32-bit GPTM block provides two 16-bit timers/counters (referred to as Timer A and Timer B) that can be configured to operate independently as timers or event counters, or concatenated to operate as one 32-bit timer or one 32-bit Real-Time Clock (RTC). Timers can also be used to trigger  $\mu$ DMA transfers.

In addition, timers can be used to trigger analog-to-digital conversions (ADC). The ADC trigger signals from all of the general-purpose timers are ORed together before reaching the ADC module, so only one timer should be used to trigger ADC events.

The GPT Module is one timing resource available on the Tiva™ C Series microcontrollers. Other timer resources include the System Timer (SysTick) (see 137) and the PWM timer in the PWM module (see “PWM Timer” on page 1547).

The General-Purpose Timer Module (GPTM) contains eight 16/32-bit GPTM blocks with the following functional options:

- Operating modes:
  - 16- or 32-bit programmable one-shot timer
  - 16- or 32-bit programmable periodic timer
  - 16-bit general-purpose timer with an 8-bit prescaler
  - 32-bit Real-Time Clock (RTC) when using an external 32.768-KHz clock as the input
  - 16-bit input-edge count- or time-capture modes with an 8-bit prescaler
  - 16-bit PWM mode with an 8-bit prescaler and software-programmable output inversion of the PWM signal
  - The System Clock or a global Alternate Clock (ALTCLK) resource can be used as timer clock source. The global ALTCLK can be:
    - PIOSC
    - Hibernation Module Real-time clock output (RTCOSC)
    - Low-frequency internal oscillator (LFIOSC)
- Count up or down
- Sixteen 16/32-bit Capture Compare PWM pins (CCP)
- Daisy chaining of timer modules to allow a single timer to initiate multiple timing events
- Timer synchronization allows selected timers to start counting on the same clock cycle
- ADC event trigger
- User-enabled stalling when the microcontroller asserts CPU Halt flag during debug (excluding RTC mode)

- Ability to determine the elapsed time between the assertion of the timer interrupt and entry into the interrupt service routine
- Efficient transfers using Micro Direct Memory Access Controller ( $\mu$ DMA)
  - Dedicated channel for each timer
  - Burst request generated on timer interrupt

## 16.1 Block Diagram

In the block diagram, the specific Capture Compare PWM (CCP) pins available depend on the TM4C129CNCZAD device. See Table 16-1 on page 1064 for the available CCP pins and their timer assignments.

Figure 16-1. GPTM Module Block Diagram

Table 16-1. Available CCP Pins

| Timer             | Up/Down Counter | Even CCP Pin | Odd CCP Pin |
|-------------------|-----------------|--------------|-------------|

## 16.2 Signal Description

The following table lists the external signals of the GP Timer module and describes the function of each. The GP Timer signals are alternate functions for some GPIO signals and default to be GPIO signals at reset. The column in the table below titled "Pin Mux/Pin Assignment" lists the possible GPIO pin placements for these GP Timer signals. The **AFSEL** bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 762) should be set to choose the GP Timer function. The number in parentheses is the encoding that must be programmed into the **PMC<sub>n</sub>** field in the **GPIO Port Control (GPIOCTL)** register (page 779) to assign the GP Timer signal to the specified GPIO port pin. For more information on configuring GPIOs, see "General-Purpose Input/Outputs (GPIOs)" on page 731.

**Table 16-2. General-Purpose Timers Signals (212BGA)**

| Pin Name | Pin Number             | Pin Mux / Pin Assignment                 | Pin Type | Buffer Type | Description                              |

### 16.3 Functional Description

The main components of each GPTM block are two free-running up/down counters (referred to as Timer A and Timer B), two prescaler registers, two match registers, two prescaler match registers, two shadow registers, and two load/initialization registers and their associated control functions. The exact functionality of each GPTM is controlled by software and configured through the register interface. Timer A and Timer B can be used individually, in which case they have a 16-bit counting range for the 16/32-bit GPTM blocks. In addition, Timer A and Timer B can be concatenated to provide a 32-bit counting range for the 16/32-bit GPTM blocks. Note that the prescaler can only be used when the timers are used individually.

The available modes for each GPTM block are shown in Table 16-3 on page 1067. Note that when counting down in one-shot or periodic modes, the prescaler acts as a true prescaler and contains the least-significant bits of the count. When counting up in one-shot or periodic modes, the prescaler acts as a timer extension and holds the most-significant bits of the count. In input edge count, input

edge time and PWM mode, the prescaler always acts as a timer extension, regardless of the count direction.

**Table 16-3. General-Purpose Timer Capabilities**

| Mode       | Timer Use    | Count Direction | Counter Size | Prescaler Size <sup>a</sup> |
|------------|--------------|-----------------|--------------|-----------------------------|
| One-shot   | Individual   | Up or Down      | 16-bit       | 8-bit                       |
|            | Concatenated | Up or Down      | 32-bit       | -                           |
| Periodic   | Individual   | Up or Down      | 16-bit       | 8-bit                       |
|            | Concatenated | Up or Down      | 32-bit       | -                           |
| RTC        | Concatenated | Up              | 32-bit       | -                           |
| Edge Count | Individual   | Up or Down      | 16-bit       | 8-bit                       |
| Edge Time  | Individual   | Up or Down      | 16-bit       | 8-bit                       |
| PWM        | Individual   | Down            | 16-bit       | 8-bit                       |

a. The prescaler is only available when the timers are used individually

Software configures the GPTM using the **GPTM Configuration (GPTMCFG)** register (see page 1085), the **GPTM Timer A Mode (GPTMTAMR)** register (see page 1086), and the **GPTM Timer B Mode (GPTMTBMR)** register (see page 1091). When in one of the concatenated modes, Timer A and Timer B can only operate in one mode. However, when configured in an individual mode, Timer A and Timer B can be independently configured in any combination of the individual modes.

### 16.3.1 GPTM Reset Conditions

After reset has been applied to the GPTM module, the module is in an inactive state, and all control registers are cleared and in their default states. Counters Timer A and Timer B are initialized to all 1s, along with their corresponding registers:

- Load Registers:
  - **GPTM Timer A Interval Load (GPTMTAILR)** register (see page 1113)
  - **GPTM Timer B Interval Load (GPTMTBILR)** register (see page 1114)
- Shadow Registers:
  - **GPTM Timer A Value (GPTMTAV)** register (see page 1123)
  - **GPTM Timer B Value (GPTMTBV)** register (see page 1124)

The following prescale counters are initialized to all 0s:

- **GPTM Timer A Prescale (GPTMTAPR)** register (see page 1117)
- **GPTM Timer B Prescale (GPTMTBPR)** register (see page 1118)
- **GPTM Timer A Prescale Snapshot (GPTMTAPS)** register (see page 1126)
- **GPTM Timer B Prescale Snapshot (GPTMTBPS)** register (see page 1127)

### 16.3.2 Timer Clock Source

The general purpose timer has the capability of being clocked by either the system clock or an alternate clock source. By setting the `ALTCLK` bit in the **GPTM Clock Configuration (GPTMCC)**

register, offset 0xFC8, software can select an alternate clock source as programmed in the **Alternate Clock Configuration (ALTCLKCFG)** register, offset 0x138 in the System Control Module. The alternate clock source options available are PIOSC, RTCOSC and LFIOOSC. Refer to “System Control” on page 222 for additional information.

**Note:** When the ALTCLK bit is set in the **GPTMCC** register to enable using the alternate clock source, the synchronization imposes restrictions on the starting count value (down-count), terminal value (up-count) and the match value. This restriction applies to all modes of operation. Each event must be spaced by 4 Timer (ALTCLK) clock periods + 2 system clock periods. If some events do not meet this requirement, then it is possible that the timer block may need to be reset for correct functionality to be restored.

Example:  $ALTCLK = T_{PIOSC} = 62.5ns$  (16Mhz Trimmed)

$T_{hclk} = 1\mu s$  (1Mhz)

$4 * 62.5ns + 2 * 1\mu s = 2.25\mu s$   $2.25\mu s / 62.5ns = 36$  or 0x23

The minimum values for the periodic or one-shot with a match interrupt enabled are:

**GPTMTAMATCHR** = 0x23 **GPTMTAILR** = 0x46

### 16.3.3 Timer Modes

This section describes the operation of the various timer modes. When using Timer A and Timer B in concatenated mode, only the Timer A control and status bits must be used; there is no need to use Timer B control and status bits. The GPTM is placed into individual/split mode by writing a value of 0x4 to the **GPTM Configuration (GPTMCFG)** register (see page 1085). In the following sections, the variable "n" is used in bit field and register names to imply either a Timer A function or a Timer B function. Throughout this section, the timeout event in down-count mode is 0x0 and in up-count mode is the value in the **GPTM Timer n Interval Load (GPTMTnILR)** and the optional **GPTM Timer n Prescale (GPTMTnPR)** registers, with the exception of RTC mode.

#### 16.3.3.1 One-Shot/Periodic Timer Mode

The selection of one-shot or periodic mode is determined by the value written to the  $T_nMR$  field of the **GPTM Timer n Mode (GPTMTnMR)** register (see page 1086). The timer is configured to count up or down using the  $T_nCDIR$  bit in the **GPTMTnMR** register.

When software sets the  $T_nEN$  bit in the **GPTM Control (GPTMCTL)** register (see page 1095), the timer begins counting up from 0x0 or down from its preloaded value. Alternatively, if the  $T_nWOT$  bit is set in the **GPTMTnMR** register, once the  $T_nEN$  bit is set, the timer waits for a trigger to begin counting (see “Wait-for-Trigger Mode” on page 1077). Table 16-4 on page 1068 shows the values that are loaded into the timer registers when the timer is enabled.

**Table 16-4. Counter Values When the Timer is Enabled in Periodic or One-Shot Modes**

| Register        | Count Down Mode  | Count Up Mode  |
|-----------------|--|--|
| <b>GPTMTnR</b>  | <b>GPTMTnILR</b>   | 0x0  |
| <b>GPTMTnV</b>  | <b>GPTMTnILR</b> in concatenated mode; <b>GPTMTnPR</b> in combination with <b>GPTMTnILR</b> in individual mode | 0x0  |
| <b>GPTMTnPS</b> | <b>GPTMTnPR</b> in individual mode; not available in concatenated mode   | 0x0 in individual mode; not available in concatenated mode |

When the timer is counting down and it reaches the timeout event (0x0), the timer reloads its start value from the **GPTMTnILR** and the **GPTMTnPR** registers on the next cycle. When the timer is counting up and it reaches the timeout event (the value in the **GPTMTnILR** and the optional

**GPTMTnPR** registers), the timer reloads with 0x0. If configured to be a one-shot timer, the timer stops counting and clears the **TnEN** bit in the **GPTMCTL** register. If configured as a periodic timer, the timer starts counting again on the next cycle.

In periodic, snap-shot mode (**TnMR** field is 0x2 and the **TnSNAPS** bit is set in the **GPTMTnMR** register), the value of the timer at the time-out event is loaded into the **GPTMTnR** register and the value of the prescaler is loaded into the **GPTMTnPS** register. The free-running counter value is shown in the **GPTMTnV** register. In this manner, software can determine the time elapsed from the interrupt assertion to the ISR entry by examining the snapshot values and the current value of the free-running timer. Snapshot mode is not available when the timer is configured in one-shot mode.

In addition to reloading the count value, the GPTM can generate interrupts, CCP outputs and triggers when it reaches the time-out event. The GPTM sets the **TnTORIS** bit in the **GPTM Raw Interrupt Status (GPTMRIS)** register (see page 1105), and holds it until it is cleared by writing the **GPTM Interrupt Clear (GPTMICR)** register (see page 1111). If the time-out interrupt is enabled in the **GPTM Interrupt Mask (GPTMIMR)** register (see page 1102), the GPTM also sets the **TnTOMIS** bit in the **GPTM Masked Interrupt Status (GPTMMIS)** register (see page 1108). The time-out interrupt can be disabled entirely by setting the **TnCINTD** bit in the **GPTM Timer n Mode (GPTMTnMR)** register. In this case, the **TnTORIS** bit does not even set in the **GPTMRIS** register.

By setting the **TnMIE** bit in the **GPTMTnMR** register, an interrupt condition can also be generated when the Timer value equals the value loaded into the **GPTM Timer n Match (GPTMTnMATCHR)** and **GPTM Timer n Prescale Match (GPTMTnPMR)** registers. This interrupt has the same status, masking, and clearing functions as the time-out interrupt, but uses the match interrupt bits instead (for example, the raw interrupt status is monitored via **TnMRIS** bit in the **GPTM Raw Interrupt Status (GPTMRIS)** register). Note that the interrupt status bits are not updated by the hardware unless the **TnMIE** bit in the **GPTMTnMR** register is set, which is different than the behavior for the time-out interrupt. The ADC trigger is enabled by setting the **TnOTE** bit in **GPTMCTL** and the event that activates the ADC is configured in the **GPTM ADC Event (GPTMADCEV)** register. The  $\mu$ DMA trigger is enabled by configuring and enabling the appropriate  $\mu$ DMA channel as well as the type of trigger enable in the **GPTM DMA Event (GPTMDMAEV)** register. See “Channel Configuration” on page 672.

The **TnCACT** field of the **GPTM Timer n Mode (GPTMTnMR)** register can be configured to clear, set or toggle an output on a time-out event.

If software updates the **GPTMTnILR** or the **GPTMTnPR** register while the counter is counting down, the counter loads the new value on the next clock cycle and continues counting from the new value if the **TnILD** bit in the **GPTMTnMR** register is clear. If the **TnILD** bit is set, the counter loads the new value after the next timeout. If software updates the **GPTMTnILR** or the **GPTMTnPR** register while the counter is counting up, the timeout event is changed on the next cycle to the new value. If software updates the **GPTM Timer n Value (GPTMTnV)** register while the counter is counting up or down, the counter loads the new value on the next clock cycle and continues counting from the new value. If software updates the **GPTMTnMATCHR** or the **GPTMTnPMR** registers, the new values are reflected on the next clock cycle if the **TnMRSU** bit in the **GPTMTnMR** register is clear. If the **TnMRSU** bit is set, the new value will not take effect until the next timeout.

If the **TnSTALL** bit in the **GPTMCTL** register is set and the **RTCEN** bit is not set in the **GPTMCTL** register, the timer freezes counting while the processor is halted by the debugger. The timer resumes counting when the processor resumes execution. If the **RTCEN** bit is set, it prevents the **TnSTALL** bit from freezing the count when the processor is halted by the debugger.

The following table shows a variety of configurations for a 16-bit free-running timer while using the prescaler. All values assume a 120-MHz clock with  $T_c=8.33$  ns (clock period). The prescaler can only be used when a 16/32-bit timer is configured in 16-bit mode.

**Table 16-5. 16-Bit Timer With Prescaler Configurations**

| Prescale (8-bit value) | # of Timer Clocks (Tc) <sup>a</sup> | Max Time | Units |
|------------------------|-------------------------------------|----------|-------|
| 00000000               | 1                                   | 0.548258 | ms    |
| 00000001               | 2                                   | 1.096517 | ms    |
| 00000010               | 3                                   | 1.644775 | ms    |
| -----                  | --                                  | --       | --    |
| 11111101               | 254                                 | 139.2576 | ms    |
| 11111110               | 255                                 | 139.8059 | ms    |
| 11111111               | 256                                 | 140.3541 | ms    |

a. Tc is the clock period.

### Timer Compare Action Mode

The timer compare mode is an extension to the GPTM's existing one-shot and periodic modes. This mode can be used when an application requires a pin change state at some time in the future, regardless of the processor state. The compare mode does not operate when the PWM mode is active and is mutually exclusive to the PWM mode. The compare mode is enabled when the TAMR field is set to 0x1 or 0x2 (one-shot or periodic), the TnAMS bit is 0 (capture or compare mode) and the TCACT field is nonzero in the **GPTM Timer n Mode (GPTMTnMR)** register. Depending on the TCACT encoding, the timer can perform a set, clear or toggle on the corresponding CCPn pin when a timer match occurs. In 16-bit mode, the corresponding CCP pin can have an action applied, but when operating in 32-bit mode, the action can only be applied to the even CCP pin.

The TCACT field can be changed while the GPTM is enabled to generate different combinations of actions. For example, during a periodic event, encodings TCACT = 0x6 or 0x7 can be used to force the initial state of the CCPn pin before the first interrupt and following that, TCACT=0x2 and TCACT=0x3 can be used (alternately) to change the sense of the pin for the subsequent toggle, while possible changing load value for the next period.

The time-out interrupts used for one-shot and periodic modes are used in the compare action modes. Thus, the TnTORIS bits in the **GPTMRIS** register are triggered if the appropriate mask bits are set in the **GPTMIM** register.

### 16.3.3.2 Real-Time Clock Timer Mode

In Real-Time Clock (RTC) mode, the concatenated versions of the Timer A and Timer B registers are configured as an up-counter. When RTC mode is selected for the first time after reset, the counter is loaded with a value of 0x1. All subsequent load values must be written to the **GPTM Timer n Interval Load (GPTMTnILR)** registers (see page 1113). If the **GPTMTnILR** register is loaded with a new value, the counter begins counting at that value and rolls over at the fixed value of 0xFFFFFFFF. Table 16-6 on page 1070 shows the values that are loaded into the timer registers when the timer is enabled.

**Table 16-6. Counter Values When the Timer is Enabled in RTC Mode**

| Register | Count Down Mode | Count Up Mode |
|----------|-----------------|---------------|
| GPTMTnR  | Not available   | 0x1           |
| GPTMTnV  | Not available   | 0x1           |
| GPTMTnPS | Not available   | Not available |

The input clock on a CCP0 input is required to be 32.768 KHz in RTC mode. The clock signal is then divided down to a 1-Hz rate and is passed along to the input of the counter.

When software writes the **TAEN** bit in the **GPTMCTL** register, the counter starts counting up from its preloaded value of 0x1. When the current count value matches the preloaded value in the **GPTMTnMATCHR** registers, the GPTM asserts the **RTC RIS** bit in **GPTMRIS** and continues counting until either a hardware reset, or it is disabled by software (clearing the **TAEN** bit). When the timer value reaches the terminal count, the timer rolls over and continues counting up from 0x0. If the RTC interrupt is enabled in **GPTMIMR**, the GPTM also sets the **RTC MIS** bit in **GPTMMIS** and generates a controller interrupt. The status flags are cleared by writing the **RTCCINT** bit in **GPTMICR**.

In this mode, the **GPTMTnR** and **GPTMTnV** registers always have the same value.

In addition to generating interrupts, the RTC can generate a  $\mu$ DMA trigger. The  $\mu$ DMA trigger is enabled by configuring and enabling the appropriate  $\mu$ DMA channel as well as the type of trigger enable in the **GPTM DMA Event (GPTMDMAEV)** register. See “Channel Configuration” on page 672.

### 16.3.3.3 Input Edge-Count Mode

**Note:** For rising-edge detection, the input signal must be High for at least two clock periods following the rising edge. Similarly, for falling-edge detection, the input signal must be Low for at least two clock periods following the falling edge. Based on this criteria, the maximum input frequency for edge detection is 1/4 of the frequency.

In Edge-Count mode, the timer is configured as a 24-bit up- or down-counter including the optional prescaler with the upper count value stored in the **GPTM Timer n Prescale (GPTMTnPR)** register and the lower bits in the **GPTMTnR** register. In this mode, the timer is capable of capturing three types of events: rising edge, falling edge, or both. To place the timer in Edge-Count mode, the **TnCMR** bit of the **GPTMTnMR** register must be cleared. The type of edge that the timer counts is determined by the **TnEVENT** fields of the **GPTMCTL** register. During initialization in down-count mode, the **GPTMTnMATCHR** and **GPTMTnPMR** registers are configured so that the difference between the value in the **GPTMTnILR** and **GPTMTnPR** registers and the **GPTMTnMATCHR** and **GPTMTnPMR** registers equals the number of edge events that must be counted. In up-count mode, the timer counts from 0x0 to the value in the **GPTMTnMATCHR** and **GPTMTnPMR** registers. Note that when executing an up-count, that the value of **GPTMTnPR** and **GPTMTnILR** must be greater than the value of **GPTMTnPMR** and **GPTMTnMATCHR**. Table 16-7 on page 1071 shows the values that are loaded into the timer registers when the timer is enabled.

**Table 16-7. Counter Values When the Timer is Enabled in Input Edge-Count Mode**

| Register       | Count Down Mode                                      | Count Up Mode |
|----------------|--|---------------|
| <b>GPTMTnR</b> | <b>GPTMTnPR</b> in combination with <b>GPTMTnILR</b> | 0x0           |
| <b>GPTMTnV</b> | <b>GPTMTnPR</b> in combination with <b>GPTMTnILR</b> | 0x0           |

When software writes the **TnEN** bit in the **GPTM Control (GPTMCTL)** register, the timer is enabled for event capture. Each input event on the CCP pin decrements or increments the counter by 1 until the event count matches **GPTMTnMATCHR** and **GPTMTnPMR**. When the counts match, the GPTM asserts the **CnMRIS** bit in the **GPTM Raw Interrupt Status (GPTMRIS)** register, and holds it until it is cleared by writing the **GPTM Interrupt Clear (GPTMICR)** register. If the capture mode match interrupt is enabled in the **GPTM Interrupt Mask (GPTMIMR)** register, the GPTM also sets the **CnMMIS** bit in the **GPTM Masked Interrupt Status (GPTMMIS)** register. In up-count mode, the current count of the input events is held in both the **GPTMTnR** and **GPTMTnV** registers. In down-count mode, the current count of the input events can be obtained by subtracting the **GPTMTnR** or **GPTMTnV** from the value made up of the **GPTMTnPR** and **GPTMTnILR** register combination.

In addition to generating interrupts, an ADC and/or a  $\mu$ DMA trigger can be generated. The ADC trigger is enabled by setting the **TnOTE** bit in **GPTMCTL** and the event that activates the ADC is configured in the **GPTM ADC Event (GPTMADCEV)** register. The  $\mu$ DMA trigger is enabled by

configuring and enabling the appropriate  $\mu$ DMA channel as well as the type of trigger enable in the **GPTM DMA Event (GPTMDMAEV)** register. See “Channel Configuration” on page 672.

After the match value is reached in down-count mode, the counter is then reloaded using the value in **GPTMTnILR** and **GPTMTnPR** registers, and stopped because the GPTM automatically clears the **TnEN** bit in the **GPTMCTL** register. Once the event count has been reached, all further events are ignored until **TnEN** is re-enabled by software. In up-count mode, the timer is reloaded with 0x0 and continues counting.

Figure 16-2 on page 1072 shows how Input Edge-Count mode works. In this case, the timer start value is set to **GPTMTnILR** = 0x000A and the match value is set to **GPTMTnMATCHR** = 0x0006 so that four edge events are counted. The counter is configured to detect both edges of the input signal.

Note that the last two edges are not counted because the timer automatically clears the **TnEN** bit after the current count matches the value in the **GPTMTnMATCHR** register.

**Figure 16-2. Input Edge-Count Mode Example, Counting Down**

### 16.3.3.4 Input Edge-Time Mode

**Note:** For rising-edge detection, the input signal must be High for at least two system clock periods following the rising edge. Similarly, for falling edge detection, the input signal must be Low for at least two system clock periods following the falling edge. Based on this criteria, the maximum input frequency for edge detection is 1/4 of the system frequency.

In Edge-Time mode, the timer is configured as a 24-bit up- or down-counter including the optional prescaler with the upper timer value stored in the **GPTMTnPR** register and the lower bits in the **GPTMTnILR** register. In this mode, the timer is initialized to the value loaded in the **GPTMTnILR** and **GPTMTnPR** registers when counting down and 0x0 when counting up. The timer is capable of capturing three types of events: rising edge, falling edge, or both. The timer is placed into Edge-Time mode by setting the **TnCMR** bit in the **GPTMTnMR** register, and the type of event that the timer captures is determined by the **TnEVENT** fields of the **GPTMCTL** register. Table 16-8 on page 1073 shows the values that are loaded into the timer registers when the timer is enabled.

**Table 16-8. Counter Values When the Timer is Enabled in Input Event-Count Mode**

| Register | Count Down Mode | Count Up Mode |
|----------|-----------------|---------------|
| TnR      | GPTMTnILR       | 0x0           |
| TnV      | GPTMTnILR       | 0x0           |

When software writes the TnEN bit in the GPTMCTL register, the timer is enabled for event capture. When the selected input event is detected, the current timer counter value is captured in the GPTMTnR and GPTMTnPS register and is available to be read by the microcontroller. The GPTM then asserts the CnERIS bit in the GPTM Raw Interrupt Status (GPTMRIS) register, and holds it until it is cleared by writing the GPTM Interrupt Clear (GPTMICR) register. If the capture mode event interrupt is enabled in the GPTM Interrupt Mask (GPTMIMR) register, the GPTM also sets the CnEMIS bit in the GPTM Masked Interrupt Status (GPTMMIS) register. In this mode, the GPTMTnR and GPTMTnPS registers hold the time at which the selected input event occurred while the GPTMTnV register holds the free-running timer value. These registers can be read to determine the time that elapsed between the interrupt assertion and the entry into the ISR.

In addition to generating interrupts, an ADC and/or a  $\mu$ DMA trigger can be generated. The ADC trigger is enabled by setting the TnOTE bit in GPTMCTL and the event that activates the ADC is configured in the GPTM ADC Event (GPTMADCEV) register. The  $\mu$ DMA trigger is enabled by configuring the appropriate  $\mu$ DMA channel as well as the type of trigger selected in the GPTM DMA Event (GPTMDMAEV) register. See “Channel Configuration” on page 672.

After an event has been captured, the timer does not stop counting. It continues to count until the TnEN bit is cleared. When the timer reaches the timeout value, it is reloaded with 0x0 in up-count mode and the value from the GPTMTnILR and GPTMTnPR registers in down-count mode.

Figure 16-3 on page 1074 shows how input edge timing mode works. In the diagram, it is assumed that the start value of the timer is the default value of 0xFFFF, and the timer is configured to capture rising edge events.

Each time a rising edge event is detected, the current count value is loaded into the GPTMTnR and GPTMTnPS registers, and is held there until another rising edge is detected (at which point the new count value is loaded into the GPTMTnR and GPTMTnPS registers).

Figure 16-3. 16-Bit Input Edge-Time Mode Example

**Note:** When operating in Edge-time mode, the counter uses a modulo  $2^{24}$  count if prescaler is enabled or  $2^{16}$ , if not. If there is a possibility the edge could take longer than the count, then another timer configured in periodic-timer mode can be implemented to ensure detection of the missed edge. The periodic timer should be configured in such a way that:

- The periodic timer cycles at the same rate as the edge-time timer
- The periodic timer interrupt has a higher interrupt priority than the edge-time timeout interrupt.
- If the periodic timer interrupt service routine is entered, software must check if an edge-time interrupt is pending and if it is, the value of the counter must be subtracted by 1 before being used to calculate the snapshot time of the event.

### 16.3.3.5 PWM Mode

The GPTM supports a simple PWM generation mode. In PWM mode, the timer is configured as a 24-bit down-counter with a start value (and thus period) defined by the **GPTMTnILR** and **GPTMTnPR** registers. In this mode, the PWM frequency and period are synchronous events and therefore guaranteed to be glitch free. PWM mode is enabled with the **GPTMTnMR** register by setting the **TnAMS** bit to 0x1, the **TnCMR** bit to 0x0, and the **TnMR** field to 0x2. Table 16-9 on page 1074 shows the values that are loaded into the timer registers when the timer is enabled.

Table 16-9. Counter Values When the Timer is Enabled in PWM Mode

| Register | Count Down Mode | Count Up Mode |
|----------|-----------------|---------------|
| GPTMTnR  | GPTMTnILR       | Not available |
| GPTMTnV  | GPTMTnILR       | Not available |

When software writes the **TnEN** bit in the **GPTMCTL** register, the counter begins counting down until it reaches the 0x0 state. Alternatively, if the **TnWOT** bit is set in the **GPTMTnMR** register, once the **TnEN** bit is set, the timer waits for a trigger to begin counting (see “Wait-for-Trigger

Mode” on page 1077). On the next counter cycle in periodic mode, the counter reloads its start value from the **GPTMTnILR** and **GPTMTnPR** registers and continues counting until disabled by software clearing the **TnEN** bit in the **GPTMCTL** register. The timer is capable of generating interrupts based on three types of events: rising edge, falling edge, or both. The event is configured by the **TnEVENT** field of the **GPTMCTL** register, and the interrupt is enabled by setting the **TnPWMIE** bit in the **GPTMTnMR** register. When the event occurs, the **CnERIS** bit is set in the **GPTM Raw Interrupt Status (GPTMRIS)** register, and holds it until it is cleared by writing the **GPTM Interrupt Clear (GPTMICR)** register. If the capture mode event interrupt is enabled in the **GPTM Interrupt Mask (GPTMIMR)** register, the GPTM also sets the **CnEMIS** bit in the **GPTM Masked Interrupt Status (GPTMMIS)** register. Note that the interrupt status bits are not updated unless the **TnPWMIE** bit is set.

In addition, when the **TnPWMIE** bit is set and a capture event occurs, the Timer automatically generates triggers to the ADC and DMA if the trigger capability is enabled by setting the **TnOTE** bit in the **GPTMCTL** register and the **CnEDMAEN** bit in the **GPTMDMAEV** register, respectively.

In this mode, the **GPTMTnR** and **GPTMTnV** registers always have the same value.

The output PWM signal asserts when the counter is at the value of the **GPTMTnILR** and **GPTMTnPR** registers (its start state), and is deasserted when the counter value equals the value in the **GPTMTnMATCHR** and **GPTMTnPMR** registers. Software has the capability of inverting the output PWM signal by setting the **TnPWML** bit in the **GPTMCTL** register.

**Note:** If PWM output inversion is enabled, edge detection interrupt behavior is reversed. Thus, if a positive-edge interrupt trigger has been set and the PWM inversion generates a positive edge, no event-trigger interrupt asserts. Instead, the interrupt is generated on the negative edge of the PWM signal.

Figure 16-4 on page 1076 shows how to generate an output PWM with a 1-ms period and a 66% duty cycle assuming a 50-MHz input clock and **TnPWML** = 0 (duty cycle would be 33% for the **TnPWML** = 1 configuration). For this example, the start value is **GPTMTnILR**=0xC350 and the match value is **GPTMTnMATCHR**=0x411A.

Figure 16-4. 16-Bit PWM Mode Example

When synchronizing the timers using the **GPTMSYNC** register, the timer must be properly configured to avoid glitches on the CCP outputs. Both the **TnPLO** and the **TnMRSU** bits must be set in the **GPTMTnMR** register. Figure 16-5 on page 1076 shows how the CCP output operates when the **TnPLO** and **TnMRSU** bits are set and the **GPTMTnMATCHR** value is greater than the **GPTMTnILR** value.

Figure 16-5. CCP Output, **GPTMTnMATCHR** > **GPTMTnILR**

Figure 16-6 on page 1077 shows how the CCP output operates when the **PLO** and **MRSU** bits are set and the **GPTMTnMATCHR** value is the same as the **GPTMTnILR** value. In this situation, if the **PLO** bit is 0, the CCP signal goes high when the **GPTMTnILR** value is loaded and the match would be essentially ignored.

**Figure 16-6. CCP Output, GPTMTnMATCHR = GPTMTnILR**

Figure 16-7 on page 1077 shows how the CCP output operates when the `PLO` and `MRSU` bits are set and the `GPTMTnILR` is greater than the `GPTMTnMATCHR` value.

**Figure 16-7. CCP Output, GPTMTnILR > GPTMTnMATCHR**

### 16.3.4 Wait-for-Trigger Mode

The Wait-for-Trigger mode allows daisy chaining of the timer modules such that once configured, a single timer can initiate multiple timing events using the Timer triggers. Wait-for-Trigger mode is enabled by setting the `TnWOT` bit in the `GPTMTnMR` register. When the `TnWOT` bit is set, Timer N+1 does not begin counting until the timer in the previous position in the daisy chain (Timer N) reaches its time-out event. The daisy chain is configured such that GPTM1 always follows GPTM0, GPTM2 follows GPTM1, and so on. If Timer A is configured as a 32-bit (16/32-bit mode) timer (controlled by the `GPTMCFG` field in the `GPTMCFG` register), it triggers Timer A in the next module. If Timer A is configured as a 16-bit (16/32-bit mode) timer, it triggers Timer B in the same module, and Timer B triggers Timer A in the next module. Figure 16-8 on page 1078 shows how the `GPTMCFG` bit affects the daisy chain. This function is valid for one-shot, periodic, and PWM modes.

**Note:** If the application requires cyclical daisy-chaining, the `TAWOT` bit in the `GPTMTAMR` register of Timer 0 can be set. In this case, Timer 0 waits for a trigger from the last timer module in the chain.

Figure 16-8. Timer Daisy Chain

### 16.3.5 Synchronizing GP Timer Blocks

The **GPTM Synchronizer Control (GPTMSYNC)** register in the GPTM0 block can be used to synchronize selected timers to begin counting at the same time. Setting a bit in the **GPTMSYNC** register causes the associated timer to perform the actions of a timeout event. An interrupt is not generated when the timers are synchronized. If a timer is being used in concatenated mode, only the bit for Timer A must be set in the **GPTMSYNC** register.

**Note:** All timers must use the same clock source for this feature to work correctly.

Table 16-10 on page 1078 shows the actions for the timeout event performed when the timers are synchronized in the various timer modes.

Table 16-10. Timeout Actions for GPTM Modes

| Mode   | Count Dir | Time Out Action   |
|--|-----------|-------------------|
| 32-bit One-Shot<br>(concatenated timers)       | —         | N/A               |
| 32-bit Periodic<br>(concatenated timers)       | Down      | Count value = ILR |
|  | Up        | Count value = 0   |
| 32-bit RTC<br>(concatenated timers)            | Up        | Count value = 0   |
| 16-bit One Shot<br>(individual/split timers)   | —         | N/A               |
| 16-bit Periodic<br>(individual/split timers)   | Down      | Count value = ILR |
|  | Up        | Count value = 0   |
| 16-bit Edge-Count<br>(individual/split timers) | Down      | Count value = ILR |
|  | Up        | Count value = 0   |
| 16-bit Edge-Time<br>(individual/split timers)  | Down      | Count value = ILR |
|  | Up        | Count value = 0   |
| 16-bit PWM                                     | Down      | Count value = ILR |

### 16.3.6 DMA Operation

The timers each have a dedicated  $\mu$ DMA channel and can provide a request signal to the  $\mu$ DMA controller. Pulse requests are generated by a timer via its own `dma_req` signal. A `dma_done` signal is provided from the  $\mu$ DMA to each timer to indicate transfer completion and trigger a  $\mu$ DMA done interrupt (`DMAnRIS`) in the **GPTM Raw Interrupt Status Register (GPTMRIS) register**. The request is a burst type and occurs whenever a timer raw interrupt condition occurs. The arbitration size of the  $\mu$ DMA transfer should be set to the amount of data that should be transferred whenever a timer event occurs.

For example, to transfer 256 items, 8 items at a time every 10 ms, configure a timer to generate a periodic timeout at 10 ms. Configure the  $\mu$ DMA transfer for a total of 256 items, with a burst size of 8 items. Each time the timer times out, the  $\mu$ DMA controller transfers 8 items, until all 256 items have been transferred. Refer to “Micro Direct Memory Access ( $\mu$ DMA)” on page 667 for more details about programming the  $\mu$ DMA controller.

A **GPTM DMA Event (GPTMDMAEV) register** is provided to enable the types of events that can cause a `dma_req` signal assertion by the timer module. Application software can enable a `dma_req` trigger for a match, capture or time-out event for each timer using the **GPTMDMAEV register**. For an individual timer, all active timer trigger events that have been enabled through the **GPTMDMAEV register** are ORed together to create a single `dma_req` pulse that is sent to the  $\mu$ DMA. When the  $\mu$ DMA transfer has completed, a `dma_done` signal is sent to the timer resulting in a `DMAnRIS` bit set in the **GPTMRIS register**.

### 16.3.7 ADC Operation

The timer has the capability to trigger the ADC when the `TnOTE` bit is set in the **GPTMCTL register** at offset 0x00C. The **GPTM ADC Event (GPTMADCEV) register** is additionally provided so that the type of ADC trigger can be defined. For example, by setting the `CBMADCEN` bit in the **GPTMADCEV register**, a trigger pulse will be sent to the ADC whenever a Capture Match event occurs in GPTM B. Similar to the  $\mu$ DMA operation, all active trigger events that have also been enabled in the **GPTMADCEV register** are ORed together to create an ADC trigger pulse.

### 16.3.8 Accessing Concatenated 16/32-Bit GPTM Register Values

The GPTM is placed into concatenated mode by writing a 0x0 or a 0x1 to the `GPTMCFG` bit field in the **GPTM Configuration (GPTMCFG) register**. In both configurations, certain 16/32-bit GPTM registers are concatenated to form pseudo 32-bit registers. These registers include:

- **GPTM Timer A Interval Load (GPTMTAILR) register** [15:0], see page 1113
- **GPTM Timer B Interval Load (GPTMTBILR) register** [15:0], see page 1114
- **GPTM Timer A (GPTMTAR) register** [15:0], see page 1121
- **GPTM Timer B (GPTMTBR) register** [15:0], see page 1122
- **GPTM Timer A Value (GPTMTAV) register** [15:0], see page 1123
- **GPTM Timer B Value (GPTMTBV) register** [15:0], see page 1124
- **GPTM Timer A Match (GPTMTAMATCHR) register** [15:0], see page 1115
- **GPTM Timer B Match (GPTMTBMATCHR) register** [15:0], see page 1116

In the 32-bit modes, the GPTM translates a 32-bit write access to **GPTMTAILR** into a write access to both **GPTMTAILR** and **GPTMTBILR**. The resulting word ordering for such a write operation is:

```
GPTMTBILR[15:0]:GPTMTAILR[15:0]
```

Likewise, a 32-bit read access to **GPTMTAR** returns the value:

```
GPTMTBR[15:0]:GPTMTAR[15:0]
```

A 32-bit read access to **GPTMTAV** returns the value:

```
GPTMTBV[15:0]:GPTMTAV[15:0]
```

## 16.4 Initialization and Configuration

To use a GPTM, the appropriate **TIMERN** bit must be set in the **RCGCTIMER** register (see page 378). If using any CCP pins, the clock to the appropriate GPIO module must be enabled via the **RCGCGPIO** register (see page 380). To find out which GPIO port to enable, refer to Table 28-4 on page 1680. Configure the **PMCn** fields in the **GPIOPCTL** register to assign the CCP signals to the appropriate pins (see page 779 and Table 28-5 on page 1693).

This section shows module initialization and configuration examples for each of the supported timer modes.

### 16.4.1 One-Shot/Periodic Timer Mode

The GPTM is configured for One-Shot and Periodic modes by the following sequence:

1. Ensure the timer is disabled (the **TnEN** bit in the **GPTMCTL** register is cleared) before making any changes.
2. Write the **GPTM Configuration Register (GPTMCFG)** with a value of 0x0000.0000.
3. Configure the **TnMR** field in the **GPTM Timer n Mode Register (GPTMTnMR)**:
  - a. Write a value of 0x1 for One-Shot mode.
  - b. Write a value of 0x2 for Periodic mode.
4. Optionally configure the **TnSNAPS**, **TnWOT**, **TnMTE**, and **TnCDIR** bits in the **GPTMTnMR** register to select whether to capture the value of the free-running timer at time-out, use an external trigger to start counting, configure an additional trigger or interrupt, and count up or down. In addition, if using CCP pins, the **TnCACT** field can be programmed to configure the compare action.
5. Load the start value into the **GPTM Timer n Interval Load Register (GPTMTnILR)**.
6. If interrupts are required, set the appropriate bits in the **GPTM Interrupt Mask Register (GPTMIMR)**.
7. Set the **TnEN** bit in the **GPTMCTL** register to enable the timer and start counting.
8. Poll the **GPTMRIS** register or wait for the interrupt to be generated (if enabled). In both cases, the status flags are cleared by writing a 1 to the appropriate bit of the **GPTM Interrupt Clear Register (GPTMICR)**.

If the `TnMIE` bit in the **GPTMTnMR** register is set, the `RTCRES` bit in the **GPTMRIS** register is set, and the timer continues counting. In One-Shot mode, the timer stops counting after the time-out event. To re-enable the timer, repeat the sequence. A timer configured in Periodic mode reloads the timer and continues counting after the time-out event.

## 16.4.2 Real-Time Clock (RTC) Mode

To use the RTC mode, the timer must have a 32.768-KHz input signal on an even CCP input. To enable the RTC feature, follow these steps:

1. Ensure the timer is disabled (the `TAEN` bit is cleared) before making any changes.
2. If the timer has been operating in a different mode prior to this, clear any residual set bits in the **GPTM Timer n Mode (GPTMTnMR)** register before reconfiguring.
3. Write the **GPTM Configuration Register (GPTMCFG)** with a value of 0x0000.0001.
4. Write the match value to the **GPTM Timer n Match Register (GPTMTnMATCHR)**.
5. Set/clear the `RTCEN` and `TnSTALL` bit in the **GPTM Control Register (GPTMCTL)** as needed.
6. If interrupts are required, set the `RTCIM` bit in the **GPTM Interrupt Mask Register (GPTMIMR)**.
7. Set the `TAEN` bit in the **GPTMCTL** register to enable the timer and start counting.

When the timer count equals the value in the **GPTMTnMATCHR** register, the GPTM asserts the `RTCRES` bit in the **GPTMRIS** register and continues counting until Timer A is disabled or a hardware reset. The interrupt is cleared by writing the `RTCCINT` bit in the **GPTMICR** register. Note that if the **GPTMTnILR** register is loaded with a new value, the timer begins counting at this new value and continues until it reaches 0xFFFF.FFFF, at which point it rolls over.

## 16.4.3 Input Edge-Count Mode

A timer is configured to Input Edge-Count mode by the following sequence:

1. Ensure the timer is disabled (the `TnEN` bit is cleared) before making any changes.
2. Write the **GPTM Configuration (GPTMCFG)** register with a value of 0x0000.0004.
3. In the **GPTM Timer Mode (GPTMTnMR)** register, write the `TnCMR` field to 0x0 and the `TnMR` field to 0x3.
4. Configure the type of event(s) that the timer captures by writing the `TnEVENT` field of the **GPTM Control (GPTMCTL)** register.
5. Program registers according to count direction:
  - In down-count mode, the **GPTMTnMATCHR** and **GPTMTnPMR** registers are configured so that the difference between the value in the **GPTMTnILR** and **GPTMTnPR** registers and the **GPTMTnMATCHR** and **GPTMTnPMR** registers equals the number of edge events that must be counted.
  - In up-count mode, the timer counts from 0x0 to the value in the **GPTMTnMATCHR** and **GPTMTnPMR** registers. Note that when executing an up-count, the value of the **GPTMTnPR** and **GPTMTnILR** must be greater than the value of **GPTMTnPMR** and **GPTMTnMATCHR**.

6. If interrupts are required, set the `CnMIM` bit in the **GPTM Interrupt Mask (GPTMIMR)** register.
7. Set the `TnEN` bit in the **GPTMCTL** register to enable the timer and begin waiting for edge events.
8. Poll the `CnMRIS` bit in the **GPTMRIS** register or wait for the interrupt to be generated (if enabled). In both cases, the status flags are cleared by writing a 1 to the `CnMCINT` bit of the **GPTM Interrupt Clear (GPTMICR)** register.

When counting down in Input Edge-Count Mode, the timer stops after the programmed number of edge events has been detected. To re-enable the timer, ensure that the `TnEN` bit is cleared and repeat steps 4 through 8.

#### 16.4.4 Input Edge Time Mode

A timer is configured to Input Edge Time mode by the following sequence:

1. Ensure the timer is disabled (the `TnEN` bit is cleared) before making any changes.
2. Write the **GPTM Configuration (GPTMCFG)** register with a value of `0x0000.0004`.
3. In the **GPTM Timer Mode (GPTMTnMR)** register, write the `TnCMR` field to `0x1` and the `TnMR` field to `0x3` and select a count direction by programming the `TnCDIR` bit.
4. Configure the type of event that the timer captures by writing the `TnEVENT` field of the **GPTM Control (GPTMCTL)** register.
5. If a prescaler is to be used, write the prescale value to the **GPTM Timer n Prescale Register (GPTMTnPR)**.
6. Load the timer start value into the **GPTM Timer n Interval Load (GPTMTnILR)** register.
7. If interrupts are required, set the `CnEIM` bit in the **GPTM Interrupt Mask (GPTMIMR)** register.
8. Set the `TnEN` bit in the **GPTM Control (GPTMCTL)** register to enable the timer and start counting.
9. Poll the `CnERIS` bit in the **GPTMRIS** register or wait for the interrupt to be generated (if enabled). In both cases, the status flags are cleared by writing a 1 to the `CnECINT` bit of the **GPTM Interrupt Clear (GPTMICR)** register. The time at which the event happened can be obtained by reading the **GPTM Timer n (GPTMTnR)** register.

In Input Edge Timing mode, the timer continues running after an edge event has been detected, but the timer interval can be changed at any time by writing the **GPTMTnILR** register and clearing the `TnILD` bit in the **GPTMTnMR** register. The change takes effect at the next cycle after the write.

#### 16.4.5 PWM Mode

A timer is configured to PWM mode using the following sequence:

1. Ensure the timer is disabled (the `TnEN` bit is cleared) before making any changes.
2. Write the **GPTM Configuration (GPTMCFG)** register with a value of `0x0000.0004`.
3. In the **GPTM Timer Mode (GPTMTnMR)** register, set the `TnAMS` bit to `0x1`, the `TnCMR` bit to `0x0`, and the `TnMR` field to `0x2`.

4. Configure the output state of the PWM signal (whether or not it is inverted) in the  $T_nPWML$  field of the **GPTM Control (GPTMCTL)** register.
5. If a prescaler is to be used, write the prescale value to the **GPTM Timer n Prescale Register (GPTMTnPR)**.
6. If PWM interrupts are used, configure the interrupt condition in the  $T_nEVENT$  field in the **GPTMCTL** register and enable the interrupts by setting the  $T_nPWMIE$  bit in the **GPTMTnMR** register. Note that edge detect interrupt behavior is reversed when the PWM output is inverted (see page 1095).
7. Load the timer start value into the **GPTM Timer n Interval Load (GPTMTnILR)** register.
8. Load the **GPTM Timer n Match (GPTMTnMATCHR)** register with the match value.
9. Set the  $T_nEN$  bit in the **GPTM Control (GPTMCTL)** register to enable the timer and begin generation of the output PWM signal.

In PWM Time mode, the timer continues running after the PWM signal has been generated. The PWM period can be adjusted at any time by writing the **GPTMTnILR** register, and the change takes effect at the next cycle after the write.

## 16.5 Register Map

Table 16-11 on page 1083 lists the GPTM registers. The offset listed is a hexadecimal increment to the register's address, relative to that timer's base address:

- 16/32-bit Timer 0: 0x4003.0000
- 16/32-bit Timer 1: 0x4003.1000
- 16/32-bit Timer 2: 0x4003.2000
- 16/32-bit Timer 3: 0x4003.3000
- 16/32-bit Timer 4: 0x4003.4000
- 16/32-bit Timer 5: 0x4003.5000
- 16/32-bit Timer 6: 0x400E.0000
- 16/32-bit Timer 7: 0x400E.1000

Note that the GP Timer module clock must be enabled before the registers can be programmed (see page 378). There must be a delay of 3 system clocks after the Timer module clock is enabled before any Timer module registers are accessed.

## 16.6 Register Descriptions

The remainder of this section lists and describes the GPTM registers, in numerical order by address offset.

**Register 1: GPTM Configuration (GPTMCFG), offset 0x000**

This register configures the global operation of the GPTM module. The value written to this register determines whether the GPTM is in 32- or 16-bit mode.

**Important:** Bits in this register should only be changed when the TAEN and TBEN bits in the GPTMCTL register are cleared.

**GPTM Configuration (GPTMCFG)**

16/32-bit Timer 0 base: 0x4003.0000  
 16/32-bit Timer 1 base: 0x4003.1000  
 16/32-bit Timer 2 base: 0x4003.2000  
 16/32-bit Timer 3 base: 0x4003.3000  
 16/32-bit Timer 4 base: 0x4003.4000  
 16/32-bit Timer 5 base: 0x4003.5000  
 16/32-bit Timer 6 base: 0x400E.0000  
 16/32-bit Timer 7 base: 0x400E.1000

## Register 2: GPTM Timer A Mode (GPTMTAMR), offset 0x004

This register configures the GPTM based on the configuration selected in the **GPTMCFG** register. When in PWM mode, set the **TAAMS** bit, clear the **TACMR** bit, and configure the **TAMR** field to 0x1 or 0x2.

This register controls the modes for Timer A when it is used individually. When Timer A and Timer B are concatenated, this register controls the modes for both Timer A and Timer B, and the contents of **GPTMTBMR** are ignored.

**Important:** Except for the **TCACT** bit field, all other bits in this register should only be changed when the **TAEN** bit in the **GPTMCTL** register is cleared.

### GPTM Timer A Mode (GPTMTAMR)

16/32-bit Timer 0 base: 0x4003.0000  
 16/32-bit Timer 1 base: 0x4003.1000

**Register 3: GPTM Timer B Mode (GPTMTBMR), offset 0x008**

This register configures the GPTM based on the configuration selected in the **GPTMCFG** register. When in PWM mode, set the **TBAMS** bit, clear the **TBCMR** bit, and configure the **TBMR** field to 0x1 or 0x2.

This register controls the modes for Timer B when it is used individually. When Timer A and Timer B are concatenated, this register is ignored and **GPTMTAMR** controls the modes for both Timer A and Timer B.

**Important:** Except for the **TCACT** bit field, all other bits in this register should only be changed when the **TBEN** bit in the **GPTMCTL** register is cleared.

**GPTM Timer B Mode (GPTMTBMR)**

16/32-bit Timer 0 base: 0x4003.0000

## Register 4: GPTM Control (GPTMCTL), offset 0x00C

This register is used alongside the **GPTMCFG** and **GMTMTnMR** registers to fine-tune the timer configuration, and to enable other features such as timer stall and the output trigger. The output trigger can be used to initiate transfers on the ADC module.

**Important:** Bits in this register should only be changed when the **TnEN** bit for the respective timer is cleared.

**Register 5: GPTM Synchronize (GPTMSYNC), offset 0x010****Note:** This register is only implemented on GPTM Module 0 only.

This register allows software to synchronize a number of timers.

## GPTM Synchronize (GPTMSYNC)

16/32-bit Timer 0 base: 0x4003.0000

16/32-bit Timer 1 base: 0x4003.1000

16/32-bit Timer 2 base: 0x4003.2000

16/32-bit Timer 3 base: 0x4003.3000

16/32-bit Timer 4 base: 0x4003.4000

16/32-bit Timer 5 base: 0x4003.5000

16/32-bit Timer 6 base: 0x400E.0000

16/32-bit Timer 7 base: 0x400E.1000

Offset 0x010

Type RW, reset 0x0000.0000

## Register 6: GPTM Interrupt Mask (GPTMIMR), offset 0x018

This register allows software to enable/disable GPTM controller-level interrupts. Setting a bit enables the corresponding interrupt, while clearing a bit disables it.

### GPTM Interrupt Mask (GPTMIMR)

**Register 7: GPTM Raw Interrupt Status (GPTMRIS), offset 0x01C**

This register shows the state of the GPTM's internal interrupt signal. These bits are set whether or not the interrupt is masked in the **GPTMIMR** register. Each bit can be cleared by writing a 1 to its corresponding bit in **GPTMICR**.

**Note:** The state of the **GPTMRIS** register is not affected by disabling and then re-enabling the timer using the **TnEN** bits in the **GPTM Control (GPTMCTL)** register. If an application requires that all or certain status bits should not carry over after re-enabling the timer, then the appropriate bits in the **GPTMRIS** register should be cleared using the **GPTMICR** register prior to re-enabling the timer. If this is not done, any status bits set in the **GPTMRIS** register and unmasked in the **GPTMIMR** register generate an interrupt once the timer is re-enabled.

**GPTM Raw Interrupt Status (GPTMRIS)**

### Register 8: GPTM Masked Interrupt Status (GPTMMIS), offset 0x020

This register show the state of the GPTM's controller-level interrupt. If an interrupt is unmasked in **GPTMIMR**, and there is an event that causes the interrupt to be asserted, the corresponding bit is set in this register. All bits are cleared by writing a 1 to the corresponding bit in **GPTMICR**.

**Register 10: GPTM Timer A Interval Load (GPTMTAILR), offset 0x028**

When the timer is counting down, this register is used to load the starting count value into the timer. When the timer is counting up, this register sets the upper bound for the timeout event.

When a GPTM is configured to one of the 32-bit modes, **GPTMTAILR** appears as a 32-bit register (the upper 16-bits correspond to the contents of the **GPTM Timer B Interval Load (GPTMTBILR)** register). In a 16-bit mode, the upper 16 bits of this register read as 0s and have no effect on the state of **GPTMTBILR**.

**GPTM Timer A Interval Load (GPTMTAILR)**

16/32-bit Timer 0 base: 0x4003.0000  
 16/32-bit Timer 1 base: 0x4003.1000  
 16/32-bit Timer 2 base: 0x4003.2000  
 16/32-bit Timer 3 base: 0x4003.3000  
 16/32-bit Timer 4 base: 0x4003.4000  
 16/32-bit Timer 5 base: 0x4003.5000

|-----------|-------|------|-------------|---|
| 31:0      | TAILR | RW   | 0xFFFF.FFFF | GPTM Timer A Interval Load Register<br>Writing this field loads the counter for Timer A. A read returns the current value of <b>GPTMTAILR</b> . |

### Register 11: GPTM Timer B Interval Load (GPTMTBILR), offset 0x02C

When the timer is counting down, this register is used to load the starting count value into the timer. When the timer is counting up, this register sets the upper bound for the timeout event.

When a GPTM is configured to one of the 32-bit modes, the contents of bits 15:0 in this register are loaded into the upper 16 bits of the **GPTMTAILR** register. Reads from this register return the current value of Timer B and writes are ignored. In a 16-bit mode, bits 15:0 are used for the load value. Bits 31:16 are reserved in both cases.

#### GPTM Timer B Interval Load (GPTMTBILR)

16/32-bit Timer 0 base: 0x4003.0000  
 16/32-bit Timer 1 base: 0x4003.1000  
 16/32-bit Timer 2 base: 0x4003.2000

**Register 12: GPTM Timer A Match (GPTMTAMATCHR), offset 0x030**

This register is loaded with a match value. Interrupts can be generated when the timer value is equal to the value in this register in one-shot or periodic mode.

In Edge-Count mode, this register along with **GPTMTAILR**, determines how many edge events are counted. The total number of edge events counted is equal to the value in **GPTMTAILR** minus this value. Note that in edge-count mode, when executing an up-count, the value of **GPTMTnPR** and **GPTMTnILR** must be greater than the value of **GPTMTnPMR** and **GPTMTnMATCHR**.

In PWM mode, this value along with **GPTMTAILR**, determines the duty cycle of the output PWM signal.

When a 16/32-bit GPTM is configured to one of the 32-bit modes, **GPTMTAMATCHR** appears as a 32-bit register (the upper 16-bits correspond to the contents of the **GPTM Timer B Match (GPTMTBMATCHR)** register). In a 16-bit mode, the upper 16 bits of this register read as 0s and have no effect on the state of **GPTMTBMATCHR**.

**GPTM Timer A Match (GPTMTAMATCHR)**

16/32-bit Timer 0 base: 0x4003.0000  
 16/32-bit Timer 1 base: 0x4003.1000

### Register 13: GPTM Timer B Match (GPTMTBMATCHR), offset 0x034

This register is loaded with a match value. Interrupts can be generated when the timer value is equal to the value in this register in one-shot or periodic mode.

In Edge-Count mode, this register along with **GPTMTBILR** determines how many edge events are counted. The total number of edge events counted is equal to the value in **GPTMTBILR** minus this value. Note that in edge-count mode, when executing an up-count, the value of **GPTMTnPR** and **GPTMTnILR** must be greater than the value of **GPTMTnPMR** and **GPTMTnMATCHR**.

In PWM mode, this value along with **GPTMTBILR**, determines the duty cycle of the output PWM signal.

When a GPTM is configured to one of the 32-bit modes, the contents of bits 15:0 in this register are loaded into the upper 16 bits of the **GPTMTAMATCHR** register. Reads from this register return the current match value of Timer B and writes are ignored. In a 16-bit mode, bits 15:0 are used for the match value. Bits 31:16 are reserved in both cases.

#### GPTM Timer B Match (GPTMTBMATCHR)

16/32-bit Timer 0 base: 0x4003.0000  
 16/32-bit Timer 1 base: 0x4003.1000

**Register 14: GPTM Timer A Prescale (GPTMTAPR), offset 0x038**

This register allows software to extend the range of the timers when they are used individually. When in one-shot or periodic down count modes, this register acts as a true prescaler for the timer counter. When acting as a true prescaler, the prescaler counts down to 0 before the value in the **GPTMTAR** and **GPTMTAV** registers are incremented. In all other individual/split modes, this register is a linear extension of the upper range of the timer counter, holding bits 23:16 in the 16-bit modes of the 16/32-bit GPTM.

### Register 15: GPTM Timer B Prescale (GPTMTBPR), offset 0x03C

This register allows software to extend the range of the timers when they are used individually. When in one-shot or periodic down count modes, this register acts as a true prescaler for the timer counter. When acting as a true prescaler, the prescaler counts down to 0 before the value in the **GPTMTBR** and **GPTMTBV** registers are incremented. In all other individual/split modes, this register is a linear extension of the upper range of the timer counter, holding bits 23:16 in the 16-bit modes of the 16/32-bit GPTM.

### Register 17: GPTM TimerB Prescale Match (GPTMTBPMR), offset 0x044

This register allows software to extend the range of the **GPTMTBMATCHR** when the timers are used individually. This register holds bits 23:16 in the 16-bit modes of the 16/32-bit GPTM.

#### GPTM TimerB Prescale Match (GPTMTBPMR)

**Register 18: GPTM Timer A (GPTMTAR), offset 0x048**

This register shows the current value of the Timer A counter in all cases except for Input Edge Count and Time modes. In the Input Edge Count mode, this register contains the number of edges that have occurred. In the Input Edge Time mode, this register contains the time at which the last edge event took place.

**Note:** When an alternate clock source is enabled, a read of this register returns the current count -1.

When a GPTM is configured to one of the 32-bit modes, **GPTMTAR** appears as a 32-bit register (the upper 16-bits correspond to the contents of the **GPTM Timer B (GPTMTBR)** register). In the 16-bit Input Edge Count, Input Edge Time, and PWM modes, bits 15:0 contain the value of the counter and bits 23:16 contain the value of the prescaler, which is the upper 8 bits of the count. Bits 31:24 always read as 0. To read the value of the prescaler in 16-bit One-Shot and Periodic modes, read bits [23:16] in the **GPTMTAV** register. To read the value of the prescaler in periodic snapshot mode, read the **Timer A Prescale Snapshot (GPTMTAPS)** register.

**GPTM Timer A (GPTMTAR)**

16/32-bit Timer 0 base: 0x4003.0000  
 16/32-bit Timer 1 base: 0x4003.1000  
 16/32-bit Timer 2 base: 0x4003.2000  
 16/32-bit Timer 3 base: 0x4003.3000  
 16/32-bit Timer 4 base: 0x4003.4000  
 16/32-bit Timer 5 base: 0x4003.5000  
 16/32-bit Timer 6 base: 0x400E.0000  
 16/32-bit Timer 7 base: 0x400E.1000  
 Offset 0x048  
 Type RO, reset 0xFFFF.FFFF

| Bit/Field | Name | Type | Reset       | Description           |
|-----------|------|------|-------------|-----------------------|
| 31:0      | TAR  | RO   | 0xFFFF.FFFF | GPTM Timer A Register |

A read returns the current value of the **GPTM Timer A Count Register**, in all cases except for Input Edge Count and Time modes. In the Input Edge Count mode, this register contains the number of edges that have occurred. In the Input Edge Time mode, this register contains the time at which the last edge event took place.

### Register 19: GPTM Timer B (GPTMTBR), offset 0x04C

This register shows the current value of the Timer B counter in all cases except for Input Edge Count and Time modes. In the Input Edge Count mode, this register contains the number of edges that have occurred. In the Input Edge Time mode, this register contains the time at which the last edge event took place.

**Note:** When an alternate clock source is enabled, a read of this register returns the current count -1.

When a GPTM is configured to one of the 32-bit modes, the contents of bits 15:0 in this register are loaded into the upper 16 bits of the **GPTMTAR** register. Reads from this register return the current value of Timer B. In a 16-bit mode, bits 15:0 contain the value of the counter and bits 23:16 contain the value of the prescaler in Input Edge Count, Input Edge Time, and PWM modes, which is the upper 8 bits of the count. Bits 31:24 always read as 0. To read the value of the prescaler in 16-bit One-Shot and Periodic modes, read bits [23:16] in the **GPTMTBV** register. To read the value of the prescaler in periodic snapshot mode, read the **Timer B Prescale Snapshot (GPTMTBPS)** register.

#### GPTM Timer B (GPTMTBR)

16/32-bit Timer 0 base: 0x4003.0000  
 16/32-bit Timer 1 base: 0x4003.1000  
 16/32-bit Timer 2 base: 0x4003.2000  
 16/32-bit Timer 3 base: 0x4003.3000  
 16/32-bit Timer 4 base: 0x4003.4000  
 16/32-bit Timer 5 base: 0x4003.5000  
 16/32-bit Timer 6 base: 0x400E.0000  
 16/32-bit Timer 7 base: 0x400E.1000  
 Offset 0x04C  
 Type RO, reset 0x0000.FFFF

| Bit/Field | Name | Type | Reset       | Description           |
|-----------|------|------|-------------|-----------------------|
| 31:0      | TBR  | RO   | 0x0000.FFFF | GPTM Timer B Register |

A read returns the current value of the **GPTM Timer B Count Register**, in all cases except for Input Edge Count and Time modes. In the Input Edge Count mode, this register contains the number of edges that have occurred. In the Input Edge Time mode, this register contains the time at which the last edge event took place.

**Register 20: GPTM Timer A Value (GPTMTAV), offset 0x050**

When read, this register shows the current, free-running value of Timer A in all modes. Software can use this value to determine the time elapsed between an interrupt and the ISR entry when using the snapshot feature with the periodic operating mode. When written, the value written into this register is loaded into the **GPTMTAR** register on the next clock cycle.

**Note:** When an alternate clock source is enabled, a read of this register returns the current count -1.

When a 16/32-bit GPTM is configured to one of the 32-bit modes, **GPTMTAV** appears as a 32-bit register (the upper 16-bits correspond to the contents of the **GPTM Timer B Value (GPTMTBV)** register). In a 16-bit mode, bits 15:0 contain the value of the counter and bits 23:16 contain the current, free-running value of the prescaler, which is the upper 8 bits of the count in Input Edge Count, Input Edge Time, PWM and one-shot or periodic up count modes. In one-shot or periodic down count modes, the prescaler stored in 23:16 is a true prescaler, meaning bits 23:16 count down before decrementing the value in bits 15:0. The prescaler in bits 31:24 always reads as 0.

**GPTM Timer A Value (GPTMTAV)**

16/32-bit Timer 0 base: 0x4003.0000  
 16/32-bit Timer 1 base: 0x4003.1000  
 16/32-bit Timer 2 base: 0x4003.2000  
 16/32-bit Timer 3 base: 0x4003.3000  
 16/32-bit Timer 4 base: 0x4003.4000  
 16/32-bit Timer 5 base: 0x4003.5000  
 16/32-bit Timer 6 base: 0x400E.0000  
 16/32-bit Timer 7 base: 0x400E.1000  
 Offset 0x050  
 Type RW, reset 0xFFFF.FFFF

| Bit/Field | Name | Type | Reset       | Description        |
|-----------|------|------|-------------|--------------------|
| 31:0      | TAV  | RW   | 0xFFFF.FFFF | GPTM Timer A Value |

A read returns the current, free-running value of Timer A in all modes. When written, the value written into this register is loaded into the **GPTMTAR** register on the next clock cycle.

**Note:** In 16-bit mode, only the lower 16-bits of the **GPTMTAV** register can be written with a new value. Writes to the prescaler bits have no effect.

### Register 21: GPTM Timer B Value (GPTMTBV), offset 0x054

When read, this register shows the current, free-running value of Timer B in all modes. Software can use this value to determine the time elapsed between an interrupt and the ISR entry. When written, the value written into this register is loaded into the **GPTMTBR** register on the next clock cycle.

**Note:** When an alternate clock source is enabled, a read of this register returns the current count -1.

When a 16/32-bit GPTM is configured to one of the 32-bit modes, the contents of bits 15:0 in this register are loaded into the upper 16 bits of the **GPTMTAV** register. Reads from this register return the current free-running value of Timer B. In a 16-bit mode, bits 15:0 contain the value of the counter and bits 23:16 contain the current, free-running value of the prescaler, which is the upper 8 bits of the count in Input Edge Count, Input Edge Time, PWM and one-shot or periodic up count modes. In one-shot or periodic down count modes, the prescaler stored in 23:16 is a true prescaler, meaning bits 23:16 count down before decrementing the value in bits 15:0. The prescaler in bits 31:24 always reads as 0.

#### GPTM Timer B Value (GPTMTBV)

16/32-bit Timer 0 base: 0x4003.0000  
 16/32-bit Timer 1 base: 0x4003.1000

|           |      |      |       | 1 Timer A and Timer B counters are 32 bits each with a 16-bit prescale counter. |

### Register 28: GPTM Clock Configuration (GPTMCC), offset 0xFC8

The **GPTMCC** register controls the clock source for the General-Purpose Timer module.

**Note:** When the **ALTCLK** bit is set in the **GPTMCC** register to enable using the alternate clock source, the synchronization imposes restrictions on the starting count value (down-count), terminal value (up-count) and the match value. This restriction applies to all modes of operation. Each event must be spaced by 4 Timer (ALTCLK) clock periods + 2 system clock periods. If some events do not meet this requirement, then it is possible that the timer block may need to be reset for correct functionality to be restored.

Example:  $ALTCLK = T_{PIOSC} = 62.5ns$  (16Mhz Trimmed)

$T_{hclk} = 1\mu s$  (1Mhz)

$4 * 62.5ns + 2 * 1\mu s = 2.25\mu s$   $2.25\mu s / 62.5ns = 36$  or 0x23

The minimum values for the periodic or one-shot with a match interrupt enabled are:  
**GPTMTAMATCHR = 0x23** **GPTMTAILR = 0x46**

#### GPTM Clock Configuration (GPTMCC)

## 17 Watchdog Timers

A watchdog timer can generate a non-maskable interrupt (NMI), a regular interrupt or a reset when a time-out value is reached. The watchdog timer is used to regain control when a system has failed due to a software error or due to the failure of an external device to respond in the expected way. The TM4C129CNCZAD microcontroller has two Watchdog Timer Modules, one module is clocked by the system clock (Watchdog Timer 0) and the other (Watchdog Timer 1) is clocked by the clock source programmed in the `ALTCLK` field of the **Alternate Clock Configuration (ALTCLKCFG)** register, System Control offset 0x138. The two modules are identical except that WDT1 is in a different clock domain, and therefore requires synchronizers. As a result, WDT1 has a bit defined in the **Watchdog Timer Control (WDTCTL)** register to indicate when a write to a WDT1 register is complete. Software can use this bit to ensure that the previous access has completed before starting the next access.

The TM4C129CNCZAD controller has two Watchdog Timer modules with the following features:

- 32-bit down counter with a programmable load register
- Separate watchdog clock with an enable
- Programmable interrupt generation logic with interrupt masking and optional NMI function
- Lock register protection from runaway software
- Reset generation logic with an enable/disable
- User-enabled stalling when the microcontroller asserts the CPU Halt flag during debug

The Watchdog Timer can be configured to generate an interrupt to the controller on its first time-out, and to generate a reset signal on its second time-out. Once the Watchdog Timer has been configured, the lock register can be written to prevent the timer configuration from being inadvertently altered.

## 17.1 Block Diagram

Figure 17-1. WDT Module Block Diagram

## 17.2 Functional Description

The Watchdog Timer module generates the first time-out signal when the 32-bit counter reaches the zero state after being enabled; enabling the counter also enables the watchdog timer interrupt. The watchdog interrupt can be programmed to be a non-maskable interrupt (NMI) using the `INTTYPE` bit in the **WDTCTL** register. After the first time-out event, the 32-bit counter is re-loaded with the value of the **Watchdog Timer Load (WDTLOAD)** register, and the timer resumes counting down from that value. Once the Watchdog Timer has been configured, the **Watchdog Timer Lock (WDTLOCK)** register is written, which prevents the timer configuration from being inadvertently altered by software.

If the timer counts down to its zero state again before the first time-out interrupt is cleared, and the reset signal has been enabled by setting the `RESEN` bit in the **WDTCTL** register, the Watchdog timer asserts its reset signal to the system. If the interrupt is cleared before the 32-bit counter reaches its second time-out, the 32-bit counter is loaded with the value in the **WDTLOAD** register, and counting resumes from that value.

If **WDTLOAD** is written with a new value while the Watchdog Timer counter is counting, then the counter is loaded with the new value and continues counting.

Writing to **WDTLOAD** does not clear an active interrupt. An interrupt must be specifically cleared by writing to the **Watchdog Interrupt Clear (WDTICR)** register.

The Watchdog module interrupt and reset generation can be enabled or disabled as required. When the interrupt is re-enabled, the 32-bit counter is preloaded with the load register value and not its last state.

The watchdog timer is disabled by default out of reset. To achieve maximum watchdog protection of the device, the watchdog timer can be enabled at the start of the reset vector.

### 17.2.1 Register Access Timing

Because the Watchdog Timer 1 module has an independent clocking domain, its registers must be written with a timing gap between accesses. Software must guarantee that this delay is inserted between back-to-back writes to WDT1 registers or between a write followed by a read to the registers. The timing for back-to-back reads from the WDT1 module has no restrictions. The **WRC** bit in the **Watchdog Control (WDTCTL)** register for WDT1 indicates that the required timing gap has elapsed. This bit is cleared on a write operation and set once the write completes, indicating to software that another write or read may be started safely. Software should poll **WDTCTL** for **WRC=1** prior to accessing another register. Note that WDT0 does not have this restriction as it runs off the system clock.

## 17.3 Initialization and Configuration

To use the WDT, its peripheral clock must be enabled by setting the **Rn** bit in the **Watchdog Timer Run Mode Clock Gating Control (RCGCWD)** register, see page 377.

The Watchdog Timer is configured using the following sequence:

1. Load the **WDTLOAD** register with the desired timer load value.
2. If WDT1, wait for the **WRC** bit in the **WDTCTL** register to be set.
3. Set the **INTEN** bit (if interrupts are required) or the **RESEN** bit (if a reset is required after two timeouts) in the **WDTCTL** register. The Watchdog Timer starts when either of them is enabled.

If software requires that all of the watchdog registers are locked, the Watchdog Timer module can be fully locked by writing any value to the **WDTLOCK** register. To unlock the Watchdog Timer, write a value of 0x1ACC.E551.

To service the watchdog, periodically reload the count value into the **WDTLOAD** register to restart the count. The interrupt can be enabled using the **INTEN** bit in the **WDTCTL** register to allow the processor to attempt corrective action if the watchdog is not serviced often enough. The **RESEN** bit in **WDTCTL** can be set so that the system resets if the failure is not recoverable using the ISR.

**Note:** The application should be sure not to modify the **ALTCLK** encoding in the **ALTCLKCFG** register while the WDT1 is enabled and running.

## 17.4 Register Map

Table 17-1 on page 1140 lists the Watchdog registers. The offset listed is a hexadecimal increment to the register's address, relative to the Watchdog Timer base address:

- WDT0: 0x4000.0000
- WDT1: 0x4000.1000

Note that the Watchdog Timer module clock must be enabled before the registers can be programmed (see page 377).

**Table 17-1. Watchdog Timers Register Map**

| Offset | Name            | Type | Reset                                    | Description                          | See page |

## 17.5 Register Descriptions

The remainder of this section lists and describes the WDT registers, in numerical order by address offset.

### Register 1: Watchdog Load (WDTLOAD), offset 0x000

This register is the 32-bit interval value used by the 32-bit counter. When this register is written, the value is immediately loaded and the counter restarts counting down from the new value. If the **WDTLOAD** register is loaded with 0x0000.0000, an interrupt is immediately generated.

#### Watchdog Load (WDTLOAD)

WDT0 base: 0x4000.0000  
 WDT1 base: 0x4000.1000  
 Offset 0x000  
 Type RW, reset 0xFFFF.FFFF

| Bit/Field | Name    | Type | Reset       | Description         |
|-----------|---------|------|-------------|---------------------|
| 31:0      | WDTLOAD | RW   | 0xFFFF.FFFF | Watchdog Load Value |

## Register 2: Watchdog Value (WDTVALUE), offset 0x004

This register contains the current count value of the timer.

### Watchdog Value (WDTVALUE)

WDT0 base: 0x4000.0000

WDT1 base: 0x4000.1000

Offset 0x004

Type RO, reset 0xFFFF.FFFF

| Bit/Field | Name     | Type | Reset       | Description   |
|-----------|----------|------|-------------|---|
| 31:0      | WDTVALUE | RO   | 0xFFFF.FFFF | Watchdog Value<br>Current value of the 32-bit down counter. |

### Register 3: Watchdog Control (WDTCTL), offset 0x008

This register is the watchdog control register. The watchdog timer can be configured to generate a reset signal (on second time-out) or an interrupt on time-out.

When the watchdog interrupt has been enabled by setting the `INTEN` bit, all subsequent writes to the `INTEN` bit are ignored. The only mechanisms that can re-enable writes to this bit are a hardware reset or a software reset initiated by setting the appropriate bit in the **Watchdog Timer Software Reset (SRWD)** register.

**Important:** Because the Watchdog Timer 1 module has an independent clocking domain, its registers must be written with a timing gap between accesses. Software must guarantee that this delay is inserted between back-to-back writes to WDT1 registers or between a write followed by a read to the registers. The timing for back-to-back reads from the WDT1 module has no restrictions. The `WRC` bit in the **Watchdog Control (WDTCTL)** register for WDT1 indicates that the required timing gap has elapsed. This bit is cleared on a write operation and set once the write completes, indicating to software that another write or read may be started safely. Software should poll **WDTCTL** for `WRC=1` prior to accessing another register. Note that WDT0 does not have this restriction as it runs off the system clock and therefore does not have a `WRC` bit.

#### Watchdog Control (WDTCTL)

WDT0 base: 0x4000.0000

WDT1 base: 0x4000.1000

Offset 0x008

Type RW, reset 0x0000.0000 (WDT0) and 0x8000.0000 (WDT1)

|       |          |          |    |    |    |    |    |    |    |    |    |    |    |    |         |       |       |

| 1         | A write access is not in progress, and WDT1 registers can be read or written. |      |           |   |       |             |   |   |   |   |
| 30:3      | reserved  | RO   | 0x000.000 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.   |       |             |   |   |   |   |

| Bit/Field | Name    | Type | Reset | Description  |
|-----------|---------|------|-------|--|
| 2         | INTTYPE | RW   | 0     | Watchdog Interrupt Type<br>The <code>INTTYPE</code> values are defined as follows:<br><br>Value Description<br>0 Watchdog interrupt is a standard interrupt.<br>1 Watchdog interrupt is a non-maskable interrupt.  |
| 1         | RESEN   | RW   | 0     | Watchdog Reset Enable<br>The <code>RESEN</code> values are defined as follows:<br><br>Value Description<br>0 Disabled.<br>1 Enable the Watchdog module reset output.<br>Setting this bit enables the Watchdog Timer.   |
| 0         | INTEN   | RW   | 0     | Watchdog Interrupt Enable<br>The <code>INTEN</code> values are defined as follows:<br><br>Value Description<br>0 Interrupt event disabled. Once this bit is set, it can only be cleared by a hardware reset or a software reset initiated by setting the appropriate bit in the <b>Watchdog Timer Software Reset (SRWD)</b> register.<br>1 Interrupt event enabled. Once enabled, all writes are ignored. Setting this bit enables the Watchdog Timer. |

**Register 4: Watchdog Interrupt Clear (WDTICR), offset 0x00C**

This register is the interrupt clear register. A write of any value to this register clears the Watchdog interrupt and reloads the 32-bit counter from the **WDTLOAD** register. Write to this register when a watchdog time-out interrupt has occurred to properly service the Watchdog. Value for a read or reset is indeterminate.

**Note:** Locking the watchdog registers by using the **WDTLOCK** register does not affect the **WDTICR** register and allows interrupts to always be serviced. Thus, a write at any time of the **WDTICR** register clears the **WDTMIS** register and reloads the 32-bit counter from the **WDTLOAD** register. The **WDTICR** register should only be written when interrupts have triggered and need to be serviced.

## Watchdog Interrupt Clear (WDTICR)

WDT0 base: 0x4000.0000

WDT1 base: 0x4000.1000

Offset 0x00C

Type WO, reset -

| Bit/Field | Name      | Type | Reset | Description   |
|-----------|-----------|------|-------|---|
| 31:0      | WDTINTCLR | WO   | -     | Watchdog Interrupt Clear<br>A write of any value to this register clears the Watchdog interrupt and reloads the 32-bit counter from the <b>WDTLOAD</b> register. Write to this register when a watchdog time-out interrupt has occurred to properly service the Watchdog. Value for a read or reset is indeterminate. |

### Register 5: Watchdog Raw Interrupt Status (WDTRIS), offset 0x010

This register is the raw interrupt status register. Watchdog interrupt events can be monitored via this register if the controller interrupt is masked.

#### Watchdog Raw Interrupt Status (WDTRIS)

WDT0 base: 0x4000.0000

|           |          |      |            | 0 The watchdog has not timed out.   |
|           |          |      |            | 1 A watchdog time-out event has occurred.   |

### Register 6: Watchdog Masked Interrupt Status (WDTMIS), offset 0x014

This register is the masked interrupt status register. The value of this register is the logical AND of the raw interrupt bit and the Watchdog interrupt enable bit.

#### Watchdog Masked Interrupt Status (WDTMIS)

WDT0 base: 0x4000.0000  
 WDT1 base: 0x4000.1000  
 Offset 0x014  
 Type RO, reset 0x0000.0000

|-----------|----------|------|-----------|---|
| 31:9      | reserved | RO   | 0x0000.00 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.   |
| 8         | STALL    | RW   | 0         | Watchdog Stall Enable<br><br>Value Description<br>0 The watchdog timer continues counting if the microcontroller is stopped with a debugger.<br>1 If the microcontroller is stopped with a debugger, the watchdog timer stops counting. Once the microcontroller is restarted, the watchdog timer resumes counting. |
| 7:0       | reserved | RO   | 0x00      | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.   |

## Register 8: Watchdog Lock (WDTLOCK), offset 0xC00

Writing 0x1ACC.E551 to the **WDTLOCK** register enables write access to all other registers. Writing any other value to the **WDTLOCK** register re-enables the locked state for register writes to all the other registers, except for the **Watchdog Test (WDTTEST)** register. Reading the **WDTLOCK** register returns the lock status rather than the 32-bit value written. Therefore, when write accesses are disabled, reading the **WDTLOCK** register returns 0x0000.0001 (when locked; otherwise, the returned value is 0x0000.0000 (unlocked)).

### Watchdog Lock (WDTLOCK)

WDT0 base: 0x4000.0000  
 WDT1 base: 0x4000.1000  
 Offset 0xC00  
 Type RW, reset 0x0000.0000

| Bit/Field | Name    | Type | Reset       | Description   |
|-----------|---------|------|-------------|---------------|
| 31:0      | WDTLOCK | RW   | 0x0000.0000 | Watchdog Lock |

A write of the value 0x1ACC.E551 unlocks the watchdog registers for write access. A write of any other value reapplies the lock, preventing any register updates, except for the **WDTTEST** register. Avoid writes to the **WDTTEST** register when the watchdog registers are locked.

A read of this register returns the following values:

| Value       | Description |
|-------------|-------------|
| 0x0000.0001 | Locked      |
| 0x0000.0000 | Unlocked    |

### Register 9: Watchdog Peripheral Identification 4 (WDTPeriphID4), offset 0xFD0

The **WDTPeriphIDn** registers are hard-coded and the fields within the register determine the reset value.

#### Watchdog Peripheral Identification 4 (WDTPeriphID4)

WDT0 base: 0x4000.0000

## 18 Analog-to-Digital Converter (ADC)

An analog-to-digital converter (ADC) is a peripheral that converts a continuous analog voltage to a discrete digital number. Two identical converter modules are included, which share 24 input channels.

The TM4C129CNCZAD ADC module features 12-bit conversion resolution and supports 24 input channels, plus an internal temperature sensor. Each ADC module contains four programmable sequencers allowing the sampling of multiple analog input sources without controller intervention. Each sample sequencer provides flexible programming with fully configurable input source, trigger events, interrupt generation, and sequencer priority. In addition, the conversion value can optionally be diverted to a digital comparator module. Each ADC module provides eight digital comparators. Each digital comparator evaluates the ADC conversion value against its two user-defined values to determine the operational range of the signal. The trigger source for ADC0 and ADC1 may be independent or the two ADC modules may operate from the same trigger source and operate on the same or different inputs. A phase shifter can delay the start of sampling by a specified phase angle. When using both ADC modules, it is possible to configure the converters to start the conversions coincidentally or within a relative phase from each other, see “Sample Phase Control” on page 1169.

The TM4C129CNCZAD microcontroller provides two ADC modules with each having the following features:

- 24 shared analog input channels
- 12-bit precision ADC
- Single-ended and differential-input configurations
- On-chip internal temperature sensor
- Maximum sample rate of two million samples/second
- Optional, programmable phase delay
- Sample and hold window programmability
- Four programmable sample conversion sequencers from one to eight entries long, with corresponding conversion result FIFOs
- Flexible trigger control
  - Controller (software)
  - Timers
  - Analog Comparators
  - PWM
  - GPIO
- Hardware averaging of up to 64 samples
- Eight digital comparators

- Converter uses two external reference signals (VREFA+ and VREFA-) or VDDA and GNDA as the voltage reference
- Power and ground for the analog circuitry is separate from the digital power and ground
- Efficient transfers using Micro Direct Memory Access Controller (μDMA)
  - Dedicated channel for each sample sequencer
  - ADC module uses burst requests for DMA
- Global Alternate Clock (ALTCLK) resource or System Clock (SYSCLK) can be used to generate ADC clock

## 18.1 Block Diagram

The TM4C129CNCZAD microcontroller contains two identical Analog-to-Digital Converter modules. These two modules, ADC0 and ADC1, share the same 24 analog input channels. Each ADC module operates independently and can therefore execute different sample sequences, sample any of the analog input channels at any time, and generate different interrupts and triggers. Figure 18-1 on page 1163 shows how the two modules are connected to analog inputs and the system bus.

**Figure 18-1. Implementation of Two ADC Blocks**

Figure 18-2 on page 1164 provides details on the internal configuration of the ADC controls and data registers.

Figure 18-2. ADC Module Block Diagram

## 18.2 Signal Description

The following table lists the external signals of the ADC module and describes the function of each. The AIN<sub>x</sub> signals are analog functions for some GPIO signals. The column in the table below titled "Pin Mux/Pin Assignment" lists the GPIO pin placement for the ADC signals. These signals are configured by clearing the corresponding DEN bit in the **GPIO Digital Enable (GPIODEN)** register and setting the corresponding AMSEL bit in the **GPIO Analog Mode Select (GPIOAMSEL)** register. For more information on configuring GPIOs, see "General-Purpose Input/Outputs (GPIOs)" on page 731. The VREFA+ and VREFA- signals (with the word "fixed" in the Pin Mux/Pin Assignment column) have a fixed pin assignment and function.

Table 18-1. ADC Signals (212BGA)

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type | Description                          |
|----------|------------|--------------------------|----------|-------------|--------------------------------------|

| AIN20    | A7         | PE6                      | I        | Analog      | Analog-to-digital converter input 20.  |
| AIN21    | B7         | PE7                      | I        | Analog      | Analog-to-digital converter input 21.  |
| AIN22    | A8         | PP7                      | I        | Analog      | Analog-to-digital converter input 22.  |
| AIN23    | B8         | PP6                      | I        | Analog      | Analog-to-digital converter input 23.  |
| VREFA+   | F4         | fixed                    | -        | Analog      | A reference voltage used to specify the voltage at which the ADC converts to a maximum value. This pin is used in conjunction with VREFA-, which specifies the minimum value. The voltage that is applied to VREFA+ is the voltage with which an AIN <sub>n</sub> signal is converted to 4095. The VREFA+ voltage is limited to the range specified in Table 29-44 on page 1748.   |
| VREFA-   | G5         | fixed                    | -        | Analog      | A reference voltage used to specify the input voltage at which the ADC converts to a minimum value. This pin is used in conjunction with VREFA+, which specifies the maximum value. In other words, the voltage that is applied to VREFA- is the voltage with which an AIN <sub>n</sub> signal is converted to 0, while the voltage that is applied to VREFA+ is the voltage with which an AIN <sub>n</sub> signal is converted to 4095. The VREFA- voltage is limited to the range specified in Table 29-44 on page 1748. |

### 18.3 Functional Description

The TM4C129CNCZAD ADC collects sample data by using a programmable sequence-based approach instead of the traditional single or double-sampling approaches found on many ADC modules. Each *sample sequence* is a fully programmed series of consecutive (back-to-back) samples, allowing the ADC to collect data from multiple input sources without having to be re-configured or serviced by the processor. The programming of each sample in the sample sequence includes parameters such as the input source and mode (differential versus single-ended input), interrupt generation on sample completion, and the indicator for the last sample in the sequence. In addition, the  $\mu$ DMA can be used to more efficiently move data from the sample sequencers without CPU intervention.

### 18.3.1 Sample Sequencers

The sampling control and data capture is handled by the sample sequencers. All of the sequencers are identical in implementation except for the number of samples that can be captured and the depth of the FIFO. Table 18-2 on page 1166 shows the maximum number of samples that each sequencer can capture and its corresponding FIFO depth. Each sample that is captured is stored in the FIFO. In this implementation, each FIFO entry is a 32-bit word, with the lower 12 bits containing the conversion result.

**Table 18-2. Samples and FIFO Depth of Sequencers**

| Sequencer | Number of Samples | Depth of FIFO |
|-----------|-------------------|---------------|
| SS3       | 1                 | 1             |
| SS2       | 4                 | 4             |
| SS1       | 4                 | 4             |
| SS0       | 8                 | 8             |

For a given sample sequence, each sample is defined by bit fields in the **ADC Sample Sequence Input Multiplexer Select (ADCSSMUXn)**, **ADC Sample Sequence Extended Input Multiplexer Select (ADCSEMUXn)** and **ADC Sample Sequence Control (ADCSSCTLn)** registers, where "n" corresponds to the sequence number. The **ADCSSMUXn** and **ADCSEMUXn** fields select the input pin, while the **ADCSSCTLn** fields contain the sample control bits corresponding to parameters such as temperature sensor selection, interrupt enable, end of sequence, and differential input mode. Sample sequencers are enabled by setting the respective **ASENn** bit in the **ADC Active Sample Sequencer (ADCACTSS)** register and should be configured before being enabled. Sampling is then initiated by setting the **SSn** bit in the **ADC Processor Sample Sequence Initiate (ADCPSSI)** register. In addition, sample sequences may be initiated on multiple ADC modules simultaneously using the **GSYNC** and **SYNCWAIT** bits in the **ADCPSSI** register during the configuration of each ADC module. For more information on using these bits, refer to page 1213.

When configuring a sample sequence, multiple uses of the same input pin within the same sequence are allowed. In the **ADCSSCTLn** register, the **IE<sub>n</sub>** bits can be set for any combination of samples, allowing interrupts to be generated after every sample in the sequence if necessary. Also, the **END** bit can be set at any point within a sample sequence. For example, if Sequencer 0 is used, the **END** bit can be set in the nibble associated with the fifth sample, allowing Sequencer 0 to complete execution of the sample sequence after the fifth sample.

After a sample sequence completes execution, the result data can be retrieved from the **ADC Sample Sequence Result FIFO (ADCSSFIFO<sub>n</sub>)** registers. The FIFOs are simple circular buffers that read a single address to "pop" result data. For software debug purposes, the positions of the FIFO head and tail pointers are visible in the **ADC Sample Sequence FIFO Status (ADCSSFSTAT<sub>n</sub>)** registers along with **FULL** and **EMPTY** status flags. If a write is attempted when the FIFO is full, the write does not occur and an overflow condition is indicated. Overflow and underflow conditions are monitored using the **ADCOSTAT** and **ADCUSTAT** registers.

### 18.3.2 Module Control

Outside of the sample sequencers, the remainder of the control logic is responsible for tasks such as:

- Interrupt generation
- DMA operation

- Sequence prioritization
- Trigger configuration
- Comparator configuration
- External voltage reference
- Sample phase control
- Module clocking

### 18.3.2.1 Interrupts

The register configurations of the sample sequencers and digital comparators dictate which events generate raw interrupts, but do not have control over whether the interrupt is actually sent to the interrupt controller. The ADC module's interrupt signals are controlled by the state of the `MASK` bits in the **ADC Interrupt Mask (ADCIM)** register. Interrupt status can be viewed at two locations: the **ADC Raw Interrupt Status (ADCRIS)** register, which shows the raw status of the various interrupt signals; and the **ADC Interrupt Status and Clear (ADCISC)** register, which shows active interrupts that are enabled by the **ADCIM** register. Sequencer interrupts are cleared by writing a 1 to the corresponding `IN` bit in **ADCISC**. Digital comparator interrupts are cleared by writing a 1 to the **ADC Digital Comparator Interrupt Status and Clear (ADCDCISC)** register.

### 18.3.2.2 DMA Operation

DMA may be used to increase efficiency by allowing each sample sequencer to operate independently and transfer data without processor intervention or reconfiguration.

The ADC asserts single and burst  $\mu$ DMA request signals (`dma_sreq` and `dma_req`) to the  $\mu$ DMA controller based on the FIFO level. The `dma_req` signal is generated when the FIFO in question is half-full (that is, at 4 samples for SS0, 2 samples for SS1 and SS2, and at 1 sample for SS3). If, for example, the **ADCSSCTL0** register has six samples to transfer, a burst of four values occurs followed by two single transfers (`dma_sreq`). The `dma_done` signals (one per sample sequencer) are sent to the ADC to allow for a triggering of `DMAINRn` interrupt bits in the **ADCRIS** register. The  $\mu$ DMA is enabled for a specific sample sequencer by setting the appropriate `ADENn` bit in the **ADCACTSS** register at offset 0x000.

To use the  $\mu$ DMA with the ADC module, the application must enable the ADC channel through **DMA Channel Map Select n (DMACHMAPn)** register in the  $\mu$ DMA.

Refer to the “Micro Direct Memory Access ( $\mu$ DMA)” on page 667 for more details about programming the  $\mu$ DMA controller.

### 18.3.2.3 Prioritization

When sampling events (triggers) happen concurrently, they are prioritized for processing by the values in the **ADC Sample Sequencer Priority (ADCSSPRI)** register. Valid priority values are in the range of 0-3, with 0 being the highest priority and 3 being the lowest. Multiple active sample sequencer units with the same priority do not provide consistent results, so software must ensure that all active sample sequencer units have a unique priority value.

### 18.3.2.4 Sampling Events

Sample triggering for each sample sequencer is defined in the **ADC Event Multiplexer Select (ADCEMUX)** register. Trigger sources include processor (default), analog comparators, an external signal on a GPIO specified by the **GPIO ADC Control (GPIOADCCTL)** register, a GP Timer, a

PWM generator, and continuous sampling. The processor triggers sampling by setting the  $SS_x$  bits in the **ADC Processor Sample Sequence Initiate (ADCPSSI)** register.

Care must be taken when using the continuous sampling trigger. If a sequencer's priority is too high, it is possible to starve other lower priority sequencers. Generally, a sample sequencer using continuous sampling should be set to the lowest priority. Continuous sampling can be used with a digital comparator to cause an interrupt when a particular voltage is seen on an input.

### 18.3.2.5 Sample and Hold Window Control

The ADC module provides the capability of programming the sample and hold window of each step in a sequence through the **ADC Sample Sequence n Sample and Hold Time (ADCSSTSHn)** register. Each  $T_{SHn}$  field can be written with a different sample and hold width, which is represented in ADC clocks. The table below gives the allowed encodings:

**Table 18-3. Sample and Hold Width in ADC Clocks**

| TSHn Encoding | $N_{SH}$ |
|---------------|----------|
| 0x0           | 4        |
| 0x1           | reserved |
| 0x2           | 8        |
| 0x3           | reserved |
| 0x4           | 16       |
| 0x5           | reserved |
| 0x6           | 32       |
| 0x7           | reserved |
| 0x8           | 64       |
| 0x9           | reserved |
| 0xA           | 128      |
| 0xB           | reserved |
| 0xC           | 256      |
| 0xD-0xF       | reserved |

The ADC conversion frequency is a function of the Sample and Hold number, given by the following equation:

$$F_{CONV} = 1 / ((N_{SH} + 12) * T_{ADC})$$

where:

- $N_{SH}$  is the sample and hold width in ADC clocks
- $T_{ADC}$  is the ADC conversion clock period, which is the inverse of the ADC clock frequency  $F_{ADC}$

Now, the maximum allowable external source resistance ( $R_S$ ) also changes with the value of  $N_{SH}$ , as the total settling time of the input circuitry must be fast enough to settle to within the ADC resolution in a single sampling interval. The input circuitry includes the external source resistance as well as the input resistance and capacitance of the ADC ( $R_{ADC}$  and  $C_{ADC}$ ).

The values for  $R_S$  and  $F_{CONV}$  for varying  $N_{SH}$  values, with  $F_{ADC}=16\text{MHz}$  and  $F_{ADC}=32\text{MHz}$  are given in tables 18-4-a and 18-4-b. The system designer must take into consideration both of these factors for optimal ADC operation.

**Table 18-4.  $R_S$  and  $F_{CONV}$  Values with Varying  $N_{SH}$  Values and  $F_{ADC} = 16$  MHz**

| $N_{SH}$ (Cycles)      | 4    | 8    | 16   | 32    | 64    | 128   | 256    |
|------------------------|------|------|------|-------|-------|-------|--------|
| $F_{CONV}$ (Ksps)      | 1000 | 800  | 571  | 364   | 211   | 114   | 60     |
| $R_S$ Max ( $\Omega$ ) | 500  | 3500 | 9500 | 21500 | 45500 | 93500 | 189500 |

**Table 18-5.  $R_S$  and  $F_{CONV}$  Values with Varying  $N_{SH}$  Values and  $F_{ADC} = 32$  MHz**

| $N_{SH}$ (Cycles)      | 4    | 8    | 16   | 32   | 64    | 128   | 256   |
|------------------------|------|------|------|------|-------|-------|-------|
| $F_{CONV}$ (Ksps)      | 2000 | 1600 | 1143 | 727  | 421   | 229   | 119   |
| $R_S$ Max ( $\Omega$ ) | 250  | 500  | 3500 | 9500 | 21500 | 45500 | 93500 |

### 18.3.2.6 Sample Phase Control

The trigger source for ADC0 and ADC1 may be independent or the two ADC modules may operate from the same trigger source and operate on the same or different inputs. If the converters are running at the same sample rate, they may be configured to start the conversions coincidentally or one ADC may be programmed to lag up to 15 clock cycles relative to the other ADC. The sample time can be delayed from the standard sampling time by programming the  $PHASE$  field in the **ADC Sample Phase Control (ADCSPC)** register. Figure 18-3 on page 1169 shows an example of various phase relationships.

**Figure 18-3. ADC Sample Phases**

This feature can be used to double the sampling rate of an input. Both ADC Module 0 and ADC Module 1 can be programmed to sample the same input. ADC module 0 can sample at the standard position (the  $PHASE$  field in the **ADCSPC** register is 0x0). ADC Module 1 can be configured to sample with a phase lag ( $PHASE$  is nonzero). For a sample rate of two million samples/second at 16MHz, the  $TSHn$  field of all of the sequencer samples of both ADCs must be programmed to 0x0 and the  $PHASE$  field of one of the ADC modules must be set to 0x8. The two modules can be synchronized using the  $GSYNC$  and  $SYNCWAIT$  bits in the **ADC Processor Sample Sequence Initiate (ADCPSSI)** register. Software can then combine the results from the two modules to create a sample rate of two million samples/second at 16MHz as shown in Figure 18-4 on page 1170.

Figure 18-4. Doubling the ADC Sample Rate

Using the **ADCSPC** register, ADC0 and ADC1 may provide a number of interesting applications:

- Coincident continuous sampling of different signals. The sample sequence steps run coincidentally in both converters. In this situation, the  $TSH_n$  of matching sample steps of both ADC module sequencers must be the same and the  $PHASE$  field must be  $0x0$  in both ADC module **ADCSPC** registers. The  $TSH_n$  field is found in the **ADC Sample Sequence n Sample and Hold Time (ADCSSTSHn)** register.

- ADC Module 0, **ADCSPC** =  $0x0$ , sampling  $A_{IN0}$
- ADC Module 1, **ADCSPC** =  $0x0$ , sampling  $A_{IN1}$

**Note:** If two ADCs are configured to sample the same signal, a skew (phase lag) must be added to one of the ADC modules to prevent coincident sampling. Phase lag can be added by programming the  $PHASE$  field in the **ADCSPC** register.

- Skewed sampling of the same signal. The skew is determined by both the  $TSH_n$  field in the **ADCSSTSHn** registers and the  $PHASE$  field in the **ADCSPC** register. For the fastest skewed sample rate, all  $TSH_n$  fields must be programmed to  $0x0$ . If  $TSH_n=0x0$  for all sequencers and the  $PHASE$  field of one ADC is  $0x8$ , the configuration doubles the conversion bandwidth of a single input when software combines the results as shown in Figure 18-5 on page 1171.

- ADC Module 0, **ADCSPC** =  $0x0$ , sampling  $A_{IN0}$
- ADC Module 1, **ADCSPC** =  $0x8$ , sampling  $A_{IN0}$

Note that it is not required that the  $TSH_n$  fields be the same in a skewed sample. If an application has varying analog input resistance, then  $TSH_n$  and  $PHASE$  may vary according to operational requirements.

Figure 18-5. Skewed Sampling

### 18.3.2.7 Module Clocking

The ADC digital block is clocked by the system clock and the ADC analog block is clocked from a separate conversion clock (ADC Clock). The ADC clock frequency can be up to 32 MHz to generate a conversion rate of 2 Msps. A 16 MHz ADC clock provides a 1 Msps sampling rate. There are three sources of the ADC clock:

- Divided PLL VCO. The PLL VCO frequency can be configured to generate up to a 32-MHz clock for a conversion rate of 2 Msps. The **CS** field in the **ADCCC** register must be programmed to 0x0 to select the PLL VCO and the **CLKDIV** field is used to set the appropriate clock divisor for the desired frequency.
- 16 MHz PIOSC. Using the PIOSC provides a conversion rate near 1 Msps. To use the PIOSC to clock the ADC, first power up the PLL and then enable the PIOSC in the **CS** bit field in the **ADCCC** register, then disable the PLL.
- MOSC. The MOSC clock source must be 16 MHz for a 1 Msps conversion rate and 32 MHz for a 2 Msps conversion rate.

The system clock must be at the same frequency or higher than the ADC clock. All ADC modules share the same clock source to facilitate the synchronization of data samples between conversion units, the selection and programming of which is provided by ADC0's **ADCCC** register. The ADC modules do not run at different conversion rates.

### 18.3.2.8 Busy Status

The **BUSY** bit of the **ADCACTSS** register is used to indicate when the ADC is busy with a current conversion. When there are no triggers pending which may start a new conversion in the immediate cycle or next few cycles, the **BUSY** bit reads as 0. Software must read the status of the **BUSY** bit as clear before disabling the ADC clock by writing to the **Analog-to-Digital Converter Run Mode Clock Gating Control (RCGCADC)** register.

### 18.3.3 Hardware Sample Averaging Circuit

Higher precision results can be generated using the hardware averaging circuit, however, the improved results are at the cost of throughput. Up to 64 samples can be accumulated and averaged to form a single data entry in the sequencer FIFO. Throughput is decreased proportionally to the number of samples in the averaging calculation. For example, if the averaging circuit is configured to average 16 samples, the throughput is decreased by a factor of 16.

By default the averaging circuit is off, and all data from the converter passes through to the sequencer FIFO. The averaging hardware is controlled by the **ADC Sample Averaging Control (ADCSAC)** register (see page 1215). A single averaging circuit has been implemented, thus all input channels receive the same amount of averaging whether they are single-ended or differential.

Figure 18-6 shows an example in which the **ADCSAC** register is set to 0x2 for 4x hardware oversampling and the **IE1** bit is set for the sample sequence, resulting in an interrupt after the second averaged value is stored in the FIFO.

**Figure 18-6. Sample Averaging Example**

### 18.3.4 Analog-to-Digital Converter

The Analog-to-Digital Converter (ADC) module uses a Successive Approximation Register (SAR) architecture to deliver a 12-bit, low-power, high-precision conversion value. The successive approximation uses a switched capacitor array to perform the dual functions of sampling and holding the signal as well as providing the 12-bit DAC operation.

Figure 18-7 shows the ADC input equivalency diagram; for parameter values, see “Analog-to-Digital Converter (ADC)” on page 1748.

Figure 18-7. ADC Input Equivalency

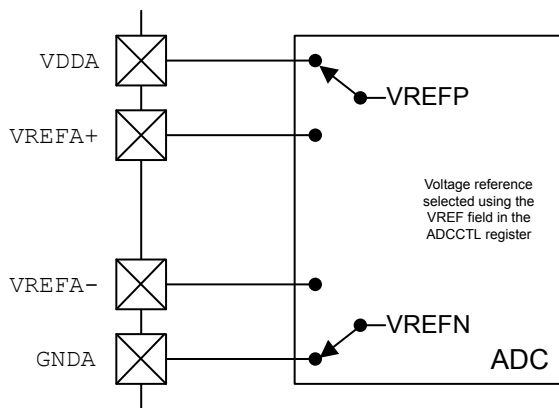

The ADC operates from both the 3.3-V analog and 1.2-V digital power supplies. The ADC clock can be configured to reduce power consumption when ADC conversions are not required (see “System Control” on page 240). The analog inputs are connected to the ADC through specially balanced input paths to minimize the distortion and cross-talk on the inputs. Detailed information on the ADC power supplies and analog inputs can be found in “Analog-to-Digital Converter (ADC)” on page 1748.

#### 18.3.4.1 Voltage Reference

The ADC uses internal signals VREFP and VREFN as references to produce a conversion value from the selected analog input. VREFP can be connected to either VREFA+ or VDDA and VREFN can be connected to either VREFA- or GNDA as configured by the VREF bit in the **ADC Control (ADCCTL)** register, as shown in Figure 18-8.

Figure 18-8. ADC Voltage Reference

The range of this conversion value is from 0x000 to 0xFFFF. In single-ended-input mode, the 0x000 value corresponds to the voltage level on VREFN; the 0xFFFF value corresponds to the voltage level on VREFP. This configuration results in a resolution that can be calculated using the following equation:

$$\text{mV per ADC code} = (V_{REFP} - V_{REFN}) / 4096$$

While the analog input pads can handle voltages beyond this range, the analog input voltages must remain within the limits prescribed by Table 29-44 on page 1748 to produce accurate results. The  $V_{REFA+}$  and  $V_{REFA-}$  specifications define the useful range for the external voltage references on  $V_{REFA+}$  and  $V_{REFA-}$ , see Table 29-44 on page 1748. Care must be taken to supply a reference voltage of acceptable quality. Figure 18-9 on page 1174 shows the ADC conversion function of the analog inputs.

Figure 18-9. ADC Conversion Result

### 18.3.5 Differential Sampling

In addition to traditional single-ended sampling, the ADC module supports differential sampling of two analog input channels. To enable differential sampling, software must set the  $D_n$  bit in the **ADCSSCTL0n** register in a step's configuration nibble.

When a sequence step is configured for differential sampling, the input pair to sample must be configured in the **ADCSSMUXn** register. Differential pair 0 samples analog inputs 0 and 1; differential

pair 1 samples analog inputs 2 and 3; and so on (see Table 18-6 on page 1175). The ADC does not support other differential pairings such as analog input 0 with analog input 3.

**Table 18-6. Differential Sampling Pairs**

| Differential Pair | Analog Inputs |
|-------------------|---------------|
| 0                 | 0 and 1       |
| 1                 | 2 and 3       |
| 2                 | 4 and 5       |
| 3                 | 6 and 7       |
| 4                 | 8 and 9       |
| 5                 | 10 and 11     |
| 6                 | 12 and 13     |
| 7                 | 14 and 15     |
| 8                 | 16 and 17     |
| 9                 | 18 and 19     |
| 10                | 20 and 21     |
| 11                | 22 and 23     |

The voltage sampled in differential mode is the difference between the odd and even channels:

- Input Positive Voltage:  $V_{IN+} = V_{IN\_EVEN}$  (even channel)
- Input Negative Voltage:  $V_{IN-} = V_{IN\_ODD}$  (odd channel)

The input differential voltage is defined as:  $V_{IN_D} = V_{IN+} - V_{IN-}$ , therefore:

- If  $V_{IN_D} = 0$ , then the conversion result = 0x800
- If  $V_{IN_D} > 0$ , then the conversion result > 0x800 (range is 0x800–0xFFF)
- If  $V_{IN_D} < 0$ , then the conversion result < 0x800 (range is 0–0x800)

When using differential sampling, the following definitions are relevant:

- Input Common Mode Voltage:  $V_{IN_{CM}} = (V_{IN+} + V_{IN-}) / 2$
- Reference Positive Voltage:  $V_{REFP}$
- Reference Negative Voltage:  $V_{REFN}$
- Reference Differential Voltage:  $V_{REF_D} = V_{REFP} - V_{REFN}$
- Reference Common Mode Voltage:  $V_{REF_{CM}} = (V_{REFP} + V_{REFN}) / 2$

The following conditions provide optimal results in differential mode:

- Both  $V_{IN\_EVEN}$  and  $V_{IN\_ODD}$  must be in the range of ( $V_{REFP}$  to  $V_{REFN}$ ) for a valid conversion result

- The maximum possible differential input swing, or the maximum differential range, is:  $-VREF_D$  to  $+VREF_D$ , so the maximum peak-to-peak input differential signal is  $(+VREF_D - -VREF_D) = 2 * VREF_D = 2 * (VREFP - VREFN)$
- In order to take advantage of the maximum possible differential input swing,  $VIN_{CM}$  should be very close to  $VREF_{CM}$ , see Table 29-44 on page 1748.

If  $VIN_{CM}$  is not equal to  $VREF_{CM}$ , the differential input signal may clip at either maximum or minimum voltage, because either single ended input can never be larger than  $VREFP$  or smaller than  $VREFN$ , and it is not possible to achieve full swing. Thus any difference in common mode between the input voltage and the reference voltage limits the differential dynamic range of the ADC.

Because the maximum peak-to-peak differential signal voltage is  $2 * (VREFP - VREFN)$ , the ADC codes are interpreted as:

$$\text{mV per ADC code} = (2 * (VREFP - VREFN)) / 4096$$

Figure 18-10 shows how the differential voltage,  $\Delta V$ , is represented in ADC codes.

**Figure 18-10. Differential Voltage Representation**

### 18.3.6 Internal Temperature Sensor

The temperature sensor serves two primary purposes: 1) to notify the system that internal temperature is too high or low for reliable operation and 2) to provide temperature measurements for calibration of the Hibernate module RTC trim value.

The temperature sensor does not have a separate enable, because it also contains the bandgap reference and must always be enabled. The reference is supplied to other analog modules; not just the ADC. In addition, the temperature sensor has a second power-down input in the 3.3 V domain which provides control by the Hibernation module.

The internal temperature sensor converts a temperature measurement into a voltage. This voltage value,  $V_{TSENS}$ , is given by the following equation (where TEMP is the temperature in °C):

$$V_{\text{TSSENS}} = 2.7 - ((\text{TEMP} + 55) / 75)$$

This relation is shown in Figure 18-11 on page 1177.

**Figure 18-11. Internal Temperature Sensor Characteristic**

The temperature sensor reading can be sampled in a sample sequence by setting the  $\text{TS}_n$  bit in the **ADCSSTLn** register. The sample and hold width should be configured for at least 16 ADC clocks using the **ADCSSTSHn** register. The temperature reading from the temperature sensor can also be given as a function of the ADC value. The following formula calculates temperature (TEMP in °C) based on the ADC reading ( $\text{ADC}_{\text{CODE}}$ , given as an unsigned decimal number from 0 to 4095) and the maximum ADC voltage range ( $\text{VREFP} - \text{VREFN}$ ):

$$\text{TEMP} = 147.5 - ((75 * (\text{VREFP} - \text{VREFN}) * \text{ADC}_{\text{CODE}}) / 4096)$$

### 18.3.7 Digital Comparator Unit

An ADC is commonly used to sample an external signal and to monitor its value to ensure that it remains in a given range. To automate this monitoring procedure and reduce the amount of processor overhead that is required, each module provides eight digital comparators.

Conversions from the ADC that are sent to the digital comparators are compared against the user programmable limits in the **ADC Digital Comparator Range (ADCDCMPn)** registers. The ADC can be configured to generate an interrupt depending on whether the ADC is operating within the low, mid or high-band region configured in the **ADCDCMPn** bit fields. The digital comparators four operational modes (Once, Always, Hysteresis Once, Hysteresis Always) can be additionally applied to the interrupt configuration.

#### 18.3.7.1 Output Functions

ADC conversions can either be stored in the ADC Sample Sequence FIFOs or compared using the digital comparator resources as defined by the  $\text{SnDCOP}$  bits in the **ADC Sample Sequence n Operation (ADCSOPn)** register. These selected ADC conversions are used by their respective

digital comparator to monitor the external signal. Each comparator has two possible output functions: processor interrupts and triggers.

Each function has its own state machine to track the monitored signal. Even though the interrupt and trigger functions can be enabled individually or both at the same time, the same conversion data is used by each function to determine if the right conditions have been met to assert the associated output.

### **Interrupts**

The digital comparator interrupt function is enabled by setting the `CIE` bit in the **ADC Digital Comparator Control (ADCDCCTLn)** register. This bit enables the interrupt function state machine to start monitoring the incoming ADC conversions. When the appropriate set of conditions is met, and the `DCONSSx` bit is set in the **ADCIM** register, an interrupt is sent to the interrupt controller.

**Note:** For a 1 to 2 Msps rate, as the system clock frequency approaches the ADC clock frequency, it is recommended that the application use the  $\mu$ DMA to store conversion data from the FIFO to memory before processing rather than an interrupt-driven single data read. Using the  $\mu$ DMA to store multiple samples before interrupting the processor amortizes interrupt overhead across multiple transfers and prevents loss of sample data.

**Note:** Only a single `DCONSSn` bit should be set at any given time. Setting more than one of these bits results in the `INRDC` bit from the **ADCRIS** register being masked, and no interrupt is generated on any of the sample sequencer interrupt lines. It is recommended that when interrupts are used, they are enabled on alternating samples or at the end of the sample sequence.

### **Triggers**

The digital comparator trigger function is enabled by setting the `CTE` bit in the **ADCDCCTLn** register. This bit enables the trigger function state machine to start monitoring the incoming ADC conversions. When the appropriate set of conditions is met, the corresponding digital comparator trigger to the PWM module is asserted.

## **18.3.7.2 Operational Modes**

Four operational modes are provided to support a broad range of applications and multiple possible signaling requirements: Always, Once, Hysteresis Always, and Hysteresis Once. The operational mode is selected using the `CIM` or `CTM` field in the **ADCDCCTLn** register.

### **Always Mode**

In the Always operational mode, the associated interrupt or trigger is asserted whenever the ADC conversion value meets its comparison criteria. The result is a string of assertions on the interrupt or trigger while the conversions are within the appropriate range.

### **Once Mode**

In the Once operational mode, the associated interrupt or trigger is asserted whenever the ADC conversion value meets its comparison criteria, and the previous ADC conversion value did not. The result is a single assertion of the interrupt or trigger when the conversions are within the appropriate range.

### **Hysteresis-Always Mode**

The Hysteresis-Always operational mode can only be used in conjunction with the low-band or high-band regions because the mid-band region must be crossed and the opposite region entered to clear the hysteresis condition. In the Hysteresis-Always mode, the associated interrupt or trigger

is asserted in the following cases: 1) the ADC conversion value meets its comparison criteria or 2) a previous ADC conversion value has met the comparison criteria, and the hysteresis condition has not been cleared by entering the opposite region. The result is a string of assertions on the interrupt or trigger that continue until the opposite region is entered.

#### ***Hysteresis-Once Mode***

The Hysteresis-Once operational mode can only be used in conjunction with the low-band or high-band regions because the mid-band region must be crossed and the opposite region entered to clear the hysteresis condition. In the Hysteresis-Once mode, the associated interrupt or trigger is asserted only when the ADC conversion value meets its comparison criteria, the hysteresis condition is clear, and the previous ADC conversion did not meet the comparison criteria. The result is a single assertion on the interrupt or trigger.

### **18.3.7.3 Function Ranges**

The two comparison values, `COMP0` and `COMP1`, in the **ADC Digital Comparator Range (ADCDCMPn)** register effectively break the conversion area into three distinct regions. These regions are referred to as the low-band (less than `COMP0`), mid-band (greater than `COMP0` but less than or equal to `COMP1`), and high-band (greater than or equal to `COMP1`) regions. `COMP0` and `COMP1` may be programmed to the same value, effectively creating two regions, but `COMP1` must always be greater than or equal to the value of `COMP0`. A `COMP1` value that is less than `COMP0` generates unpredictable results.

#### ***Low-Band Operation***

To operate in the low-band region, the `CIC` field or the `CTC` field in the **ADCDCCTLn** register must be programmed to `0x0`. This setting causes interrupts or triggers to be generated in the low-band region as defined by the programmed operational mode. An example of the state of the interrupt/trigger signal in the low-band region for each of the operational modes is shown in Figure 18-12 on page 1180. Note that a "0" in a column following the operational mode name (Always, Once, Hysteresis Always, and Hysteresis Once) indicates that the interrupt or trigger signal is deasserted and a "1" indicates that the signal is asserted.

Figure 18-12. Low-Band Operation (CIC=0x0 and/or CTC=0x0)

**Mid-Band Operation**

To operate in the mid-band region, the **CIC** field or the **CTC** field in the **ADCDCCTLn** register must be programmed to 0x1. This setting causes interrupts or triggers to be generated in the mid-band region according the operation mode. Only the Always and Once operational modes are available in the mid-band region. An example of the state of the interrupt/trigger signal in the mid-band region for each of the allowed operational modes is shown in Figure 18-13 on page 1181. Note that a "0" in a column following the operational mode name (Always or Once) indicates that the interrupt or trigger signal is deasserted and a "1" indicates that the signal is asserted.

Figure 18-13. Mid-Band Operation (CIC=0x1 and/or CTC=0x1)

### High-Band Operation

To operate in the high-band region, the `CIC` field or the `CTC` field in the `ADCDCCTLn` register must be programmed to `0x3`. This setting causes interrupts or triggers to be generated in the high-band region according to the operation mode. An example of the state of the interrupt/trigger signal in the high-band region for each of the allowed operational modes is shown in Figure 18-14 on page 1182. Note that a "0" in a column following the operational mode name (Always, Once, Hysteresis Always, and Hysteresis Once) indicates that the interrupt or trigger signal is deasserted and a "1" indicates that the signal is asserted.

Figure 18-14. High-Band Operation (CIC=0x3 and/or CTC=0x3)

## 18.4 Initialization and Configuration

### 18.4.1 Module Initialization

Initialization of the ADC module is a simple process with very few steps: enabling the clock to the ADC, disabling the analog isolation circuit associated with all inputs that are to be used, and reconfiguring the sample sequencer priorities (if needed).

The initialization sequence for the ADC is as follows:

1. Enable the ADC clock using the **RCGCADC** register (see page 393).
2. Enable the clock to the appropriate GPIO modules via the **RCGCGPIO** register (see page 380). To find out which GPIO ports to enable, refer to “Signal Description” on page 1164.
3. Set the GPIO **AFSEL** bits for the ADC input pins (see page 762). To determine which GPIOs to configure, see Table 28-4 on page 1680.
4. Configure the **AIN<sub>x</sub>** signals to be analog inputs by clearing the corresponding **DEN** bit in the **GPIO Digital Enable (GPIODEN)** register (see page 773).
5. Disable the analog isolation circuit for all ADC input pins that are to be used by writing a 1 to the appropriate bits of the **GPIOAMSEL** register (see page 778) in the associated GPIO block.
6. If required by the application, reconfigure the sample sequencer priorities in the **ADCSSPRI** register. The default configuration has Sample Sequencer 0 with the highest priority and Sample Sequencer 3 as the lowest priority.

## 18.4.2 Sample Sequencer Configuration

Configuration of the sample sequencers is slightly more complex than the module initialization because each sample sequencer is completely programmable.

The configuration for each sample sequencer should be as follows:

1. Ensure that the sample sequencer is disabled by clearing the corresponding `ASENn` bit in the **ADCACTSS** register. Programming of the sample sequencers is allowed without having them enabled. Disabling the sequencer during programming prevents erroneous execution if a trigger event were to occur during the configuration process.
2. Configure the trigger event for the sample sequencer in the **ADCEMUX** register.
3. When using a PWM generator as the trigger source, use the **ADC Trigger Source Select (ADCTSSEL)** register to specify in which PWM module the generator is located. The default register reset selects PWM module 0 for all generators.
4. For each sample in the sample sequence, configure the corresponding input source in the **ADCSSMUX<sub>n</sub>** and **ADCSEMUX<sub>n</sub>** registers.
5. For each sample in the sample sequence, configure the sample control bits in the corresponding nibble in the **ADCSSCTL<sub>n</sub>** register. When programming the last nibble, ensure that the `END` bit is set. Failure to set the `END` bit causes unpredictable behavior.
6. If interrupts are to be used, set the corresponding `MASK` bit in the **ADCIM** register.
7. Enable the sample sequencer logic by setting the corresponding `ASENn` bit in the **ADCACTSS** register.

## 18.5 Register Map

Table 18-7 on page 1183 lists the ADC registers. The offset listed is a hexadecimal increment to the register's address, relative to that ADC module's base address of:

- ADC0: 0x4003.8000
- ADC1: 0x4003.9000

Note that the ADC module clock must be enabled before the registers can be programmed (see page 393). There must be a delay of 3 system clocks after the ADC module clock is enabled before any ADC module registers are accessed.

**Table 18-7. ADC Register Map**

| Offset | Name     | Type | Reset       | Description                    | See page |
|--------|----------|------|-------------|--------------------------------|----------|

## **18.6 Register Descriptions**

The remainder of this section lists and describes the ADC registers, in numerical order by address offset.

**Register 1: ADC Active Sample Sequencer (ADCACTSS), offset 0x000**

This register controls the activation of the sample sequencers. Each sample sequencer can be enabled or disabled independently.

**ADC Active Sample Sequencer (ADCACTSS)**

ADC0 base: 0x4003.8000  
 ADC1 base: 0x4003.9000  
 Offset 0x000

### Register 3: ADC Interrupt Mask (ADCIM), offset 0x008

This register controls whether the sample sequencer and digital comparator raw interrupt signals are sent to the interrupt controller. Each raw interrupt signal can be masked independently.

**Note:** For a 1 to 2 Msps rate, as the system clock frequency approaches the ADC clock frequency, it is recommended that the application use the  $\mu$ DMA to store conversion data from the FIFO to memory before processing rather than an interrupt-driven single data read. Using the  $\mu$ DMA to store multiple samples before interrupting the processor amortizes interrupt overhead across multiple transfers and prevents loss of sample data.

**Note:** Only a single  $DCONSS_n$  bit should be set at any given time. Setting more than one of these bits results in the  $INRDC$  bit from the **ADCRIS** register being masked, and no interrupt is generated on any of the sample sequencer interrupt lines. It is recommended that when interrupts are used, they are enabled on alternating samples or at the end of the sample sequence.

## Register 4: ADC Interrupt Status and Clear (ADCISC), offset 0x00C

This register provides the mechanism for clearing sample sequencer interrupt conditions and shows the status of interrupts generated by the sample sequencers and the digital comparators which have been sent to the interrupt controller. When read, each bit field is the logical AND of the respective **INR** and **MASK** bits. Sample sequencer interrupts are cleared by writing a 1 to the corresponding bit position. Digital comparator interrupts are cleared by writing a 1 to the appropriate bits in the **ADCDCISC** register. If software is polling the **ADCRIS** instead of generating interrupts, the sample sequence **INR<sub>n</sub>** bits are still cleared via the **ADCISC** register, even if the **IN<sub>n</sub>** bit is not set.

### ADC Interrupt Status and Clear (ADCISC)

**Register 5: ADC Overflow Status (ADCOSTAT), offset 0x010**

This register indicates overflow conditions in the sample sequencer FIFOs. Once the overflow condition has been handled by software, the condition can be cleared by writing a 1 to the corresponding bit position.

**ADC Overflow Status (ADCOSTAT)**

ADC0 base: 0x4003.8000  
 ADC1 base: 0x4003.9000  
 Offset 0x010  
 Type RW1C, reset 0x0000.0000

**Register 6: ADC Event Multiplexer Select (ADCEMUX), offset 0x014**

The **ADCEMUX** selects the event (trigger) that initiates sampling for each sample sequencer. Each sample sequencer can be configured with a unique trigger source.

### Register 7: ADC Underflow Status (ADCUSTAT), offset 0x018

This register indicates underflow conditions in the sample sequencer FIFOs. The corresponding underflow condition is cleared by writing a 1 to the relevant bit position.

#### ADC Underflow Status (ADCUSTAT)

## Register 8: ADC Trigger Source Select (ADCTSSEL), offset 0x01C

If a PWM Generator  $n$  is selected as a trigger source through the  $EM_n$  bit field in the **ADC Event Multiplexer Select (ADCEMUX)** register, the **ADCTSSEL** register is programmed to identify in which PWM module instance the generator creating the trigger is located. The register resets to 0x0000.0000, which selects PWM module 0 for all generators. Note that field  $PS_3$  selects the PWM module that maps to Generator 3;  $PS_2$  selects the PWM module that maps to Generator 2, and so on.

### ADC Trigger Source Select (ADCTSSEL)

**Register 9: ADC Sample Sequencer Priority (ADCSSPRI), offset 0x020**

This register sets the priority for each of the sample sequencers. Out of reset, Sequencer 0 has the highest priority, and Sequencer 3 has the lowest priority. When reconfiguring sequence priorities, each sequence must have a unique priority for the ADC to operate properly.

**ADC Sample Sequencer Priority (ADCSSPRI)**

## Register 10: ADC Sample Phase Control (ADCSPC), offset 0x024

The **ADC Sample Phase Control (ADCSPC)** register is used to insert a delay in ADC module sampling. This feature can be used with the **SYNCWAIT** and **GSYNC** bit in the **ADCPSSI** register to provide concurrent sampling of two different signals by two different ADC modules or skewed sampling of two ADC modules to increase the effective sampling rate. For concurrent sampling, the **PHASE** field of each ADC module must be the same and the sample and hold times (**TSH<sub>n</sub>**) for the matching sample steps of each ADC must be the same. For example, both ADC0 and ADC1 would program **PHASE = 0x0** in the **ADCSPC** register and might both have the following configuration for their **ADCSSTSH0** register:

- TSH7=0x4
- TSH6=0x2
- TSH5=0x2
- TSH4=0x8
- TSH3=0x6
- TSH2=0x2
- TSH1=0x4
- TSH0=0x2

For skewed sampling with a consistent phase lag, the **TSH<sub>n</sub>** field in the **ADCSSTSH<sub>n</sub>** register must be the same for all sample steps of an ADC and for both ADC Modules. The desired lag can be calculated by adding the sample and hold time (**TSH<sub>n</sub>**) to the twelve clock conversion time to determine the total number of clocks in a sample period. For example to create a 180.0° phase lag, the **PHASE** of the lagging ADC is calculated as:

$$\text{PHASE} = (\text{TSH}_n + 12)/2, \text{ where TSH}_n \text{ is in ADC\_Clocks}$$

For situations where a predictable phase lag is not required, sample and hold times (**TSH<sub>n</sub>**) of ADC modules can vary.

**Note:** Care should be taken when the **PHASE** field is non-zero, as the resulting delay in sampling the **AIN<sub>x</sub>** input may result in undesirable system consequences. The time from ADC trigger to sample is increased and could make the response time longer than anticipated. The added latency could have ramifications in the system design. Designers should carefully consider the impact of this delay.

**Register 11: ADC Processor Sample Sequence Initiate (ADCPSSI), offset 0x028**

This register provides a mechanism for application software to initiate sampling in the sample sequencers. Sample sequences can be initiated individually or in any combination. When multiple sequences are triggered simultaneously, the priority encodings in **ADCSSPRI** dictate execution order.

This register also provides a means to configure and then initiate concurrent sampling on all ADC modules. To do this, the first ADC module should be configured. The **ADCPSSI** register for that module should then be written. The appropriate **SS** bits should be set along with the **SYNCWAIT** bit. Additional ADC modules should then be configured following the same procedure. Once the final ADC module is configured, its **ADCPSSI** register should be written with the appropriate **SS** bits set along with the **GSYNC** bit. All of the ADC modules then begin concurrent sampling according to their configuration.

**Register 12: ADC Sample Averaging Control (ADCSAC), offset 0x030**

This register controls the amount of hardware averaging applied to conversion results. The final conversion result stored in the FIFO is averaged from  $2^{\text{AVG}}$  consecutive ADC samples at the specified ADC speed. If AVG is 0, the sample is passed directly through without any averaging. If AVG=6, then 64 consecutive ADC samples are averaged to generate one result in the sequencer FIFO. An AVG=7 provides unpredictable results.

### Register 14: ADC Control (ADCCTL), offset 0x038

This register configures the voltage reference. The voltage references for the conversion can be  $V_{REFA+}$  and  $V_{REFA-}$  or  $V_{DDA}$  and  $G_{NDA}$ . Note that values set in this register apply to all ADC modules, it is not possible to set one module to use internal references and another to use external references.

## Register 15: ADC Sample Sequence Input Multiplexer Select 0 (ADCSSMUX0), offset 0x040

This register, along with the **ADCSSMUX0** register, defines the analog input configuration for each sample in a sequence executed with Sample Sequencer 0. If the corresponding **EMUX<sub>n</sub>** bit in the **ADCSSMUX0** register is set, the **MUX<sub>n</sub>** field in this register selects from **AIN[23:16]**. When the corresponding **EMUX<sub>n</sub>** bit is clear, the **MUX<sub>n</sub>** field selects from **AIN[15:0]**. This register is 32 bits wide and contains information for eight possible samples.

**Note:** Channels **AIN[31:24]** do not exist on this microcontroller. Configuring **MUX<sub>n</sub>** to be 0x8-0xF when the corresponding **EMUX<sub>n</sub>** bit is set results in undefined behavior.

### ADC Sample Sequence Input Multiplexer Select 0 (ADCSSMUX0)

## Register 16: ADC Sample Sequence Control 0 (ADCSSCTL0), offset 0x044

This register contains the configuration information for each sample for a sequence executed with a sample sequencer. When configuring a sample sequence, the `END` bit must be set for the final sample, whether it be after the first sample, eighth sample, or any sample in between. This register is 32 bits wide and contains information for eight possible samples.

| 3         | TS0  | RW   | 0     | <p>1st Sample Temp Sensor Select</p> <p>Value Description</p> <p>0 The input pin specified by the <b>ADCSSMUXn</b> register is read during the first sample of the sample sequence.</p> <p>1 The temperature sensor is read during the first sample of the sample sequence.</p>   |
| 2         | IE0  | RW   | 0     | <p>1st Sample Interrupt Enable</p> <p>Value Description</p> <p>0 The raw interrupt is not asserted to the interrupt controller.</p> <p>1 The raw interrupt signal (<b>INR0</b> bit) is asserted at the end of the first sample's conversion. If the <b>MASK0</b> bit in the <b>ADCIM</b> register is set, the interrupt is promoted to the interrupt controller.</p> <p>It is legal to have multiple samples within a sequence generate interrupts.</p>                   |
| 1         | END0 | RW   | 0     | <p>1st Sample is End of Sequence</p> <p>Value Description</p> <p>0 Another sample in the sequence is the final sample.</p> <p>1 The first sample is the last sample of the sequence.</p> <p>It is possible to end the sequence on any sample position. Software must set an <b>ENDn</b> bit somewhere within the sequence. Samples defined after the sample containing a set <b>ENDn</b> bit are not requested for conversion even though the fields may be non-zero.</p> |
| 0         | D0   | RW   | 0     | <p>1st Sample Differential Input Select</p> <p>Value Description</p> <p>0 The analog inputs are not differentially sampled.</p> <p>1 The analog input is differentially sampled. The corresponding <b>ADCSSMUXn</b> nibble must be set to the pair number "i", where the paired inputs are "2i and 2i+1".</p> <p>Because the temperature sensor does not have a differential option, this bit must not be set when the <b>TS0</b> bit is set.</p>                         |

**Register 17: ADC Sample Sequence Result FIFO 0 (ADCSSFIFO0), offset 0x048**

**Register 18: ADC Sample Sequence Result FIFO 1 (ADCSSFIFO1), offset 0x068**

**Register 19: ADC Sample Sequence Result FIFO 2 (ADCSSFIFO2), offset 0x088**

**Register 20: ADC Sample Sequence Result FIFO 3 (ADCSSFIFO3), offset 0x0A8**

**Important:** This register is read-sensitive. See the register description for details.

This register contains the conversion results for samples collected with the sample sequencer (the **ADCSSFIFO0** register is used for Sample Sequencer 0, **ADCSSFIFO1** for Sequencer 1, **ADCSSFIFO2** for Sequencer 2, and **ADCSSFIFO3** for Sequencer 3). Reads of this register return conversion result data in the order sample 0, sample 1, and so on, until the FIFO is empty. If the FIFO is not properly handled by software, overflow and underflow conditions are registered in the **ADCOSTAT** and **ADCUSTAT** registers.

ADC Sample Sequence Result FIFO n (ADCSSFIFO<sub>n</sub>)

ADC0 base: 0x4003.8000

ADC1 base: 0x4003.9000

Offset 0x048

Type RO, reset -

| Bit/Field | Name     | Type | Reset    | Description   |
|-----------|----------|------|----------|---|
| 31:12     | reserved | RO   | 0x0000.0 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 11:0      | DATA     | RO   | -        | Conversion Result Data  |

**Register 21: ADC Sample Sequence FIFO 0 Status (ADCSSFSTAT0), offset 0x04C**

**Register 22: ADC Sample Sequence FIFO 1 Status (ADCSSFSTAT1), offset 0x06C**

**Register 23: ADC Sample Sequence FIFO 2 Status (ADCSSFSTAT2), offset 0x08C**

**Register 24: ADC Sample Sequence FIFO 3 Status (ADCSSFSTAT3), offset 0x0AC**

This register provides a window into the sample sequencer, providing full/empty status information as well as the positions of the head and tail pointers. The reset value of 0x100 indicates an empty FIFO with the head and tail pointers both pointing to index 0. The **ADCSSFSTAT0** register provides status on FIFO0, which has 8 entries; **ADCSSFSTAT1** on FIFO1, which has 4 entries; **ADCSSFSTAT2** on FIFO2, which has 4 entries; and **ADCSSFSTAT3** on FIFO3 which has a single entry.

## Register 26: ADC Sample Sequence 0 Digital Comparator Select (ADCSSDC0), offset 0x054

This register determines which digital comparator receives the sample from the given conversion on Sample Sequence 0, if the corresponding  $S_nDCOP$  bit in the **ADCSSOP0** register is set.

### ADC Sample Sequence 0 Digital Comparator Select (ADCSSDC0)

## Register 27: ADC Sample Sequence Extended Input Multiplexer Select 0 (ADCSEMUX0), offset 0x058

This register, along with the **ADCSSMUX0** register, defines the analog input configuration for each sample in a sequence executed with Sample Sequencer 0. If a bit in this register is set, the corresponding **MUX<sub>n</sub>** field in the **ADCSSMUX0** register selects from **AIN[23:16]**. When a bit in this register is clear, the corresponding **MUX<sub>n</sub>** field selects from **AIN[15:0]**. This register is 32 bits wide and contains information for eight possible samples.

Note that this register is not used when the differential channel designation is used (the **D<sub>n</sub>** bit is set in the **ADCSSCTL0** register) because the **ADCSSMUX0** register can select all the available pairs.

## Register 28: ADC Sample Sequence 0 Sample and Hold Time (ADCSSTSH0), offset 0x05C

This register controls the sample period size for each sample of sequencer 0. Each sample and hold period select specifies the time allocated to the sample and hold circuit as shown by the encodings in Table 18-3 on page 1168.

**Note:** If sampling the internal temperature sensor, the sample and hold width should be at least 16 ADC clocks ( $T_{SHn} = 0x4$ ).

**Table 18-8. Sample and Hold Width in ADC Clocks**

| TSHn Encoding | N <sub>SH</sub> |

**Register 29: ADC Sample Sequence Input Multiplexer Select 1 (ADCSSMUX1), offset 0x060****Register 30: ADC Sample Sequence Input Multiplexer Select 2 (ADCSSMUX2), offset 0x080**

This register, along with the **ADCSSMUX1** or **ADCSSMUX2** register, defines the analog input configuration for each sample in a sequence executed with Sample Sequencer 1 or 2. If the corresponding **EMUX<sub>n</sub>** bit in the **ADCSSMUX1** or **ADCSSMUX2** register is set, the **MUX<sub>n</sub>** field in this register selects from **AIN[23:16]**. When the corresponding **EMUX<sub>n</sub>** bit is clear, the **MUX<sub>n</sub>** field selects from **AIN[15:0]**. These registers are 16 bits wide and contain information for four possible samples. See the **ADCSSMUX0** register on page 1219 for detailed bit descriptions. The **ADCSSMUX1** register affects Sample Sequencer 1 and the **ADCSSMUX2** register affects Sample Sequencer 2.

**Note:** Channels **AIN[31:24]** do not exist on this microcontroller. Configuring **MUX<sub>n</sub>** to be 0x8-0xF when the corresponding **EMUX<sub>n</sub>** bit is set results in undefined behavior.

**Register 31: ADC Sample Sequence Control 1 (ADCSSCTL1), offset 0x064**

**Register 32: ADC Sample Sequence Control 2 (ADCSSCTL2), offset 0x084**

These registers contain the configuration information for each sample for a sequence executed with Sample Sequencer 1 or 2. When configuring a sample sequence, the **END** bit must be set for the final sample, whether it be after the first sample, fourth sample, or any sample in between. These registers are 16-bits wide and contain information for four possible samples. See the **ADCSSCTL0** register on page 1221 for detailed bit descriptions. The **ADCSSCTL1** register configures Sample Sequencer 1 and the **ADCSSCTL2** register configures Sample Sequencer 2.

**Register 33: ADC Sample Sequence 1 Operation (ADCSSOP1), offset 0x070**

**Register 34: ADC Sample Sequence 2 Operation (ADCSSOP2), offset 0x090**

This register determines whether the sample from the given conversion on Sample Sequence n is saved in the Sample Sequence n FIFO or sent to the digital comparator unit. The **ADCSSOP1** register controls Sample Sequencer 1 and the **ADCSSOP2** register controls Sample Sequencer 2.

ADC Sample Sequence n Operation (ADCSSOPn)

**Register 35: ADC Sample Sequence 1 Digital Comparator Select (ADCSSDC1), offset 0x074****Register 36: ADC Sample Sequence 2 Digital Comparator Select (ADCSSDC2), offset 0x094**

These registers determine which digital comparator receives the sample from the given conversion on Sample Sequence n if the corresponding  $S_nDCOP$  bit in the **ADCSSOPn** register is set. The **ADCSSDC1** register controls the selection for Sample Sequencer 1 and the **ADCSSDC2** register controls the selection for Sample Sequencer 2.

## Register 37: ADC Sample Sequence Extended Input Multiplexer Select 1 (ADCSEMUX1), offset 0x078

## Register 38: ADC Sample Sequence Extended Input Multiplexer Select 2 (ADCSEMUX2), offset 0x098

This register, along with the **ADCSSMUX1** or **ADCSSMUX2** register, defines the analog input configuration for each sample in a sequence executed with either Sample Sequencer 1 or 2. If a bit in this register is set, the corresponding **MUX<sub>n</sub>** field in the **ADCSSMUX1** or **ADCSSMUX2** register selects from **AIN[23:16]**. When a bit in this register is clear, the corresponding **MUX<sub>n</sub>** field selects from **AIN[15:0]**. This register is 16 bits wide and contains information for four possible samples. The **ADCSEMUX1** register controls Sample Sequencer 1 and the **ADCSEMUX2** register controls Sample Sequencer 2.

Note that this register is not used when the differential channel designation is used (the **D<sub>n</sub>** bit is set in the **ADCSSCTL1** or **ADCSSCTL2** register) because the **ADCSSMUX1** or **ADCSSMUX2** register can select all the available pairs.

**Register 39: ADC Sample Sequence 1 Sample and Hold Time (ADCSSTSH1), offset 0x07C****Register 40: ADC Sample Sequence 2 Sample and Hold Time (ADCSSTSH2), offset 0x09C**

These registers control the sample period size for each sample step of sequencer 1 and sequencer 2. Each sample and hold period select specifies the time allocated to the sample and hold circuit as shown by the encodings in Table 18-3 on page 1168.

**Note:** If sampling the internal temperature sensor, the sample and hold width should be at least 16 ADC clocks ( $T_{SHn} = 0x4$ ).

**Table 18-9. Sample and Hold Width in ADC Clocks**

| TSHn Encoding | N <sub>SH</sub> |

## Register 41: ADC Sample Sequence Input Multiplexer Select 3 (ADCSSMUX3), offset 0x0A0

This register, along with the **ADCSEMUX3** register, defines the analog input configuration for the sample in a sequence executed with Sample Sequencer 3. If the **EMUX0** bit in the **ADCSEMUX3** register is set, the **MUX0** field in this register selects from **AIN[23:16]**. When the **EMUX0** bit is clear, the **MUX0** field selects from **AIN[15:0]**. This register is four bits wide and contains information for one possible sample. See the **ADCSSMUX0** register on page 1219 for detailed bit descriptions.

### Register 42: ADC Sample Sequence Control 3 (ADCSSCTL3), offset 0x0A4

This register contains the configuration information for a sample executed with Sample Sequencer 3. This register is 4 bits wide and contains information for one possible sample. See the **ADCSSCTL0** register on page 1221 for detailed bit descriptions.

**Note:** When configuring a sample sequence in this register, the **END0** bit must be set.

**Note:** Values not listed are reserved.

| Value | Description  |
|-------|--|
| 0x0   | Digital Comparator Unit 0 ( <b>ADCDCCMP0</b> and <b>ADCCCTL0</b> ) |
| 0x1   | Digital Comparator Unit 1 ( <b>ADCDCCMP1</b> and <b>ADCCCTL1</b> ) |
| 0x2   | Digital Comparator Unit 2 ( <b>ADCDCCMP2</b> and <b>ADCCCTL2</b> ) |
| 0x3   | Digital Comparator Unit 3 ( <b>ADCDCCMP3</b> and <b>ADCCCTL3</b> ) |
| 0x4   | Digital Comparator Unit 4 ( <b>ADCDCCMP4</b> and <b>ADCCCTL4</b> ) |
| 0x5   | Digital Comparator Unit 5 ( <b>ADCDCCMP5</b> and <b>ADCCCTL5</b> ) |
| 0x6   | Digital Comparator Unit 6 ( <b>ADCDCCMP6</b> and <b>ADCCCTL6</b> ) |
| 0x7   | Digital Comparator Unit 7 ( <b>ADCDCCMP7</b> and <b>ADCCCTL7</b> ) |

### Register 45: ADC Sample Sequence Extended Input Multiplexer Select 3 (ADCSEMUX3), offset 0x0B8

This register, along with the **ADCSSMUX3** register, defines the analog input configuration for the sample in a sequence executed with Sample Sequencer 3. If **EMUX0** is set, the **MUX0** field in the **ADCSSMUX3** register selects from **AIN[23:16]**. When **EMUX0** is clear, the **MUX0** field selects from **AIN[15:0]**. This register is 1 bit wide and contains information for one possible sample.

Note that this register is not used when the differential channel designation is used (the **Dn** bit is set in the **ADCSSCTL3** register) because the **ADCSSMUX3** register can select all the available pairs.

#### ADC Sample Sequence Extended Input Multiplexer Select 3 (ADCSEMUX3)

ADC0 base: 0x4003.8000  
 ADC1 base: 0x4003.9000  
 Offset 0x0B8

| Bit/Field | Name     | Type | Reset      | Description   |
|-----------|----------|------|------------|---|
| 31:1      | reserved | RO   | 0x0000.000 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 0         | EMUX0    | RW   | 0x0        | 1st Sample Input Select (Upper Bit)<br>The <b>EMUX0</b> field is used during the only sample of a sequence executed with the sample sequencer.  |
|           |          |      |            | Value Description   |
|           |          |      |            | 0 The sample input is selected from <b>AIN[15:0]</b> using the <b>ADCSSMUX3</b> register. For example, if the <b>MUX0</b> field is 0x0, <b>AIN0</b> is selected.                              |
|           |          |      |            | 1 The sample input is selected from <b>AIN[23:16]</b> using the <b>ADCSSMUX3</b> register. For example, if the <b>MUX0</b> field is 0x0, <b>AIN16</b> is selected.                            |

## Register 46: ADC Sample Sequence 3 Sample and Hold Time (ADCSSTSH3), offset 0x0BC

This register controls the sample period size for the sample in sequencer 3. The sample and hold period select specifies the time allocated to the sample and hold circuit as shown by the encodings in Table 18-3 on page 1168

**Note:** If sampling the internal temperature sensor, the sample and hold width should be at least 16 ADC clocks ( $T_{SHn} = 0x4$ ).

**Table 18-10. Sample and Hold Width in ADC Clocks**

| TSHn Encoding | N <sub>SH</sub> |
|---------------|-----------------|
| 0x0           | 4               |

## Register 47: ADC Digital Comparator Reset Initial Conditions (ADCDCRIC), offset 0xD00

This register provides the ability to reset any of the digital comparator interrupt or trigger functions back to their initial conditions. Resetting these functions ensures that the data that is being used by the interrupt and trigger functions in the digital comparator unit is not stale.

### ADC Digital Comparator Reset Initial Conditions (ADCDCRIC)

ADC0 base: 0x4003.8000  
 ADC1 base: 0x4003.9000  
 Offset 0xD00  
 Type WO, reset 0x0000.0000

#### Value Description

|   |   |
|---|---|
| 0 | Disables the trigger function state machine. ADC conversion data is ignored by the trigger function.  |
| 1 | Enables the trigger function state machine. The ADC conversion data is used to determine if a trigger should be generated according to the programming of the CTC and CTM fields. |

**Register 56: ADC Digital Comparator Range 0 (ADCDCMP0), offset 0xE40**

**Register 57: ADC Digital Comparator Range 1 (ADCDCMP1), offset 0xE44**

**Register 58: ADC Digital Comparator Range 2 (ADCDCMP2), offset 0xE48**

**Register 59: ADC Digital Comparator Range 3 (ADCDCMP3), offset 0xE4C**

**Register 60: ADC Digital Comparator Range 4 (ADCDCMP4), offset 0xE50**

**Register 61: ADC Digital Comparator Range 5 (ADCDCMP5), offset 0xE54**

**Register 62: ADC Digital Comparator Range 6 (ADCDCMP6), offset 0xE58**

**Register 63: ADC Digital Comparator Range 7 (ADCDCMP7), offset 0xE5C**

This register defines the comparison values that are used to determine if the ADC conversion data falls in the appropriate operating region.

**Note:** The value in the COMP1 field must be greater than or equal to the value in the COMP0 field or unexpected results can occur.

ADC Digital Comparator Range n (ADCDCMPn)

## 19 Universal Asynchronous Receivers/Transmitters (UARTs)

The TM4C129CNCZAD controller includes eight Universal Asynchronous Receiver/Transmitter (UART) with the following features:

- Programmable baud-rate generator allowing speeds up to 7.5 Mbps for regular speed (divide by 16) and 15 Mbps for high speed (divide by 8)
- Separate 16x8 transmit (TX) and receive (RX) FIFOs to reduce CPU interrupt service loading
- Programmable FIFO length, including 1-byte deep operation providing conventional double-buffered interface
- FIFO trigger levels of 1/8, 1/4, 1/2, 3/4, and 7/8
- Standard asynchronous communication bits for start, stop, and parity
- Line-break generation and detection
- Fully programmable serial interface characteristics
  - 5, 6, 7, or 8 data bits
  - Even, odd, stick, or no-parity bit generation/detection
  - 1 or 2 stop bit generation
- IrDA serial-IR (SIR) encoder/decoder providing
  - Programmable use of IrDA Serial Infrared (SIR) or UART input/output
  - Support of IrDA SIR encoder/decoder functions for data rates up to 115.2 Kbps half-duplex
  - Support of normal 3/16 and low-power (1.41-2.23  $\mu$ s) bit durations
  - Programmable internal clock generator enabling division of reference clock by 1 to 256 for low-power mode bit duration
- Support for communication with ISO 7816 smart cards
- Modem functionality available on the following UARTs:
  - UART0 (modem flow control and modem status)
  - UART1 (modem flow control and modem status)
  - UART2 (modem flow control)
  - UART3 (modem flow control)
  - UART4 (modem flow control)
- EIA-485 9-bit support

- Standard FIFO-level and End-of-Transmission interrupts
- Efficient transfers using Micro Direct Memory Access Controller (μDMA)
  - Separate channels for transmit and receive
  - Receive single request asserted when data is in the FIFO; burst request asserted at programmed FIFO level
  - Transmit single request asserted when there is space in the FIFO; burst request asserted at programmed FIFO level
- Global Alternate Clock (ALTCLK) resource or System Clock (SYSCLK) can be used to generate baud clock

## 19.1 Block Diagram

Figure 19-1. UART Module Block Diagram

## 19.2 Signal Description

The following table lists the external signals of the UART module and describes the function of each. The UART signals are alternate functions for some GPIO signals and default to be GPIO signals at reset. The column in the table below titled "Pin Mux/Pin Assignment" lists the possible GPIO pin

placements for these UART signals. The **AFSEL** bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 762) should be set to choose the UART function. The number in parentheses is the encoding that must be programmed into the **PMC<sub>n</sub>** field in the **GPIO Port Control (GPIOCTL)** register (page 779) to assign the UART signal to the specified GPIO port pin. For more information on configuring GPIOs, see “General-Purpose Input/Outputs (GPIOs)” on page 731.

### 19.3 Functional Description

Each TM4C129CNCZAD UART performs the functions of parallel-to-serial and serial-to-parallel conversions. It is similar in functionality to a 16C550 UART, but is not register compatible.

The UART is configured for transmit and/or receive via the TXE and RXE bits of the **UART Control (UARTCTL)** register (see page 1299). Transmit and receive are both enabled out of reset. Before any

control registers are programmed, the UART must be disabled by clearing the `UARTEN` bit in `UARTCTL`. If the UART is disabled during a TX or RX operation, the current transaction is completed prior to the UART stopping.

The UART module also includes a serial IR (SIR) encoder/decoder block that can be connected to an infrared transceiver to implement an IrDA SIR physical layer. The SIR function is programmed using the `UARTCTL` register.

### 19.3.1 Transmit/Receive Logic

The transmit logic performs parallel-to-serial conversion on the data read from the transmit FIFO. The control logic outputs the serial bit stream beginning with a start bit and followed by the data bits (LSB first), parity bit, and the stop bits according to the programmed configuration in the control registers. See Figure 19-2 on page 1275 for details.

The receive logic performs serial-to-parallel conversion on the received bit stream after a valid start pulse has been detected. Overrun, parity, frame error checking, and line-break detection are also performed, and their status accompanies the data that is written to the receive FIFO.

**Figure 19-2. UART Character Frame**

### 19.3.2 Baud-Rate Generation

The baud-rate divisor is a 22-bit number consisting of a 16-bit integer and a 6-bit fractional part. The number formed by these two values is used by the baud-rate generator to determine the bit period. Having a fractional baud-rate divisor allows the UART to generate all the standard baud rates.

The 16-bit integer is loaded through the **UART Integer Baud-Rate Divisor (UARTIBRD)** register (see page 1295) and the 6-bit fractional part is loaded with the **UART Fractional Baud-Rate Divisor (UARTFBRD)** register (see page 1296). The baud-rate divisor (BRD) has the following relationship to the system clock (where *BRDI* is the integer part of the BRD and *BRDF* is the fractional part, separated by a decimal place.)

$$BRD = BRDI + BRDF = \text{UARTSysClk} / (\text{ClkDiv} * \text{Baud Rate})$$

where `UARTSysClk` is the system clock connected to the UART, and `ClkDiv` is either 16 (if `HSE` in `UARTCTL` is clear) or 8 (if `HSE` is set). By default, this will be the main system clock described in “Clock Control” on page 232. Alternatively, the UART may be clocked from the internal precision oscillator (PIOSC), independent of the system clock selection. This will allow the UART clock to be programmed independently of the system clock PLL settings. See the `UARTCC` register for more details.

The 6-bit fractional number (that is to be loaded into the `DIVFRAC` bit field in the `UARTFBRD` register) can be calculated by taking the fractional part of the baud-rate divisor, multiplying it by 64, and adding 0.5 to account for rounding errors:

$$\text{UARTFBRD}[\text{DIVFRAC}] = \text{integer}(\text{BRDF} * 64 + 0.5)$$

The UART generates an internal baud-rate reference clock at 8x or 16x the baud-rate (referred to as `Baud8` and `Baud16`, depending on the setting of the `HSE` bit (bit 5) in `UARTCTL`). This reference clock is divided by 8 or 16 to generate the transmit clock, and is used for error detection during

receive operations. Note that the state of the `HSE` bit has no effect on clock generation in ISO 7816 smart card mode (when the `SMART` bit in the `UARTCTL` register is set).

Along with the **UART Line Control, High Byte (UARTLCRH)** register (see page 1297), the `UARTIBRD` and `UARTFBRD` registers form an internal 30-bit register. This internal register is only updated when a write operation to `UARTLCRH` is performed, so any changes to the baud-rate divisor must be followed by a write to the `UARTLCRH` register for the changes to take effect.

To update the baud-rate registers, there are four possible sequences:

- `UARTIBRD` write, `UARTFBRD` write, and `UARTLCRH` write
- `UARTFBRD` write, `UARTIBRD` write, and `UARTLCRH` write
- `UARTIBRD` write and `UARTLCRH` write
- `UARTFBRD` write and `UARTLCRH` write

### 19.3.3 Data Transmission

Data received or transmitted is stored in two 16-byte FIFOs, though the receive FIFO has an extra four bits per character for status information. For transmission, data is written into the transmit FIFO. If the UART is enabled, it causes a data frame to start transmitting with the parameters indicated in the `UARTLCRH` register. Data continues to be transmitted until there is no data left in the transmit FIFO. The `BUSY` bit in the **UART Flag (UARTFR)** register (see page 1291) is asserted as soon as data is written to the transmit FIFO (that is, if the FIFO is non-empty) and remains asserted while data is being transmitted. The `BUSY` bit is negated only when the transmit FIFO is empty, and the last character has been transmitted from the shift register, including the stop bits. The UART can indicate that it is busy even though the UART may no longer be enabled.

When the receiver is idle (the `UnRx` signal is continuously 1), and the data input goes Low (a start bit has been received), the receive counter begins running and data is sampled on the eighth cycle of `Baud16` or fourth cycle of `Baud8` depending on the setting of the `HSE` bit (bit 5) in `UARTCTL` (described in “Transmit/Receive Logic” on page 1275).

The start bit is valid and recognized if the `UnRx` signal is still low on the eighth cycle of `Baud16` (`HSE` clear) or the fourth cycle of `Baud 8` (`HSE` set), otherwise it is ignored. After a valid start bit is detected, successive data bits are sampled on every 16th cycle of `Baud16` or 8th cycle of `Baud8` (that is, one bit period later) according to the programmed length of the data characters and value of the `HSE` bit in `UARTCTL`. The parity bit is then checked if parity mode is enabled. Data length and parity are defined in the `UARTLCRH` register.

Lastly, a valid stop bit is confirmed if the `UnRx` signal is High, otherwise a framing error has occurred. When a full word is received, the data is stored in the receive FIFO along with any error bits associated with that word.

### 19.3.4 Serial IR (SIR)

The UART peripheral includes an IrDA serial-IR (SIR) encoder/decoder block. The IrDA SIR block provides functionality that converts between an asynchronous UART data stream and a half-duplex serial SIR interface. No analog processing is performed on-chip. The role of the SIR block is to provide a digital encoded output and decoded input to the UART. When enabled, the SIR block uses the `UnTx` and `UnRx` pins for the SIR protocol. These signals should be connected to an infrared transceiver to implement an IrDA SIR physical layer link. The SIR block can receive and transmit, but it is only half-duplex so it cannot do both at the same time. Transmission must be stopped before

data can be received. The IrDA SIR physical layer specifies a minimum 10-ms delay between transmission and reception. The SIR block has two modes of operation:

- In normal IrDA mode, a zero logic level is transmitted as a high pulse of  $\frac{3}{16}$ th duration of the selected baud rate bit period on the output pin, while logic one levels are transmitted as a static LOW signal. These levels control the driver of an infrared transmitter, sending a pulse of light for each zero. On the reception side, the incoming light pulses energize the photo transistor base of the receiver, pulling its output LOW and driving the UART input pin LOW.
- In low-power IrDA mode, the width of the transmitted infrared pulse is set to three times the period of the internally generated IrLPBaud16 signal (1.63  $\mu$ s, assuming a nominal 1.8432 MHz frequency) by changing the appropriate bit in the **UARTCTL** register (see page 1299).

Whether the device is in normal or low-power IrDA mode, a start bit is deemed valid if the decoder is still Low, one period of IrLPBaud16 after the Low was first detected. This enables a normal-mode UART to receive data from a low-power mode UART that can transmit pulses as small as 1.41  $\mu$ s. Thus, for both low-power and normal mode operation, the **ILPDVSR** field in the **UARTILPR** register must be programmed such that  $1.42 \text{ MHz} < F_{\text{IrLPBaud16}} < 2.12 \text{ MHz}$ , resulting in a low-power pulse duration of 1.41–2.11  $\mu$ s (three times the period of IrLPBaud16). The minimum frequency of IrLPBaud16 ensures that pulses less than one period of IrLPBaud16 are rejected, but pulses greater than 1.4  $\mu$ s are accepted as valid pulses.

Figure 19-3 on page 1277 shows the UART transmit and receive signals, with and without IrDA modulation.

**Figure 19-3. IrDA Data Modulation**

In both normal and low-power IrDA modes:

- During transmission, the UART data bit is used as the base for encoding
- During reception, the decoded bits are transferred to the UART receive logic

The IrDA SIR physical layer specifies a half-duplex communication link, with a minimum 10-ms delay between transmission and reception. This delay must be generated by software because it is not automatically supported by the UART. The delay is required because the infrared receiver electronics might become biased or even saturated from the optical power coupled from the adjacent transmitter LED. This delay is known as latency or receiver setup time.

### 19.3.5 ISO 7816 Support

The UART offers basic support to allow communication with an ISO 7816 smartcard. When bit 3 ( $\overline{SMART}$ ) of the **UARTCTL** register is set, the  $\overline{UnTx}$  signal is used as a bit clock, and the  $\overline{UnRx}$  signal is used as the half-duplex communication line connected to the smartcard. A GPIO signal can be used to generate the reset signal to the smartcard. The remaining smartcard signals should be provided by the system design. The maximum clock rate in this mode is system clock / 16.

When using ISO 7816 mode, the **UARTLCRH** register must be set to transmit 8-bit words ( $\overline{WLEN}$  bits 6:5 configured to 0x3) with EVEN parity ( $\overline{PEN}$  set and  $\overline{EPS}$  set). In this mode, the UART automatically uses 2 stop bits, and the  $\overline{STP2}$  bit of the **UARTLCRH** register is ignored.

If a parity error is detected during transmission,  $\overline{UnRx}$  is pulled Low during the second stop bit. In this case, the UART aborts the transmission, flushes the transmit FIFO and discards any data it contains, and raises a parity error interrupt, allowing software to detect the problem and initiate retransmission of the affected data. Note that the UART does not support automatic retransmission in this case.

### 19.3.6 Modem Handshake Support

This section describes how to configure and use the modem flow control and status signals for a UART when connected as a DTE (data terminal equipment) or as a DCE (data communications equipment). In general, a modem is a DCE and a computing device that connects to a modem is the DTE.

#### 19.3.6.1 Signaling

The status signals provided by a UART differ based on whether the UART is used as a DTE or DCE. When used as a DTE, the modem flow control and status signals are defined as:

- $\overline{UnCTS}$  is Clear To Send
- $\overline{UnDSR}$  is Data Set Ready
- $\overline{UnDCD}$  is Data Carrier Detect
- $\overline{UnRI}$  is Ring Indicator
- $\overline{UnRTS}$  is Request To Send
- $\overline{UnDTR}$  is Data Terminal Ready

When used as a DCE, the modem flow control and status signals are defined as:

- $\overline{UnCTS}$  is Request To Send
- $\overline{UnDSR}$  is Data Terminal Ready
- $\overline{UnRTS}$  is Clear To Send
- $\overline{UnDTR}$  is Data Set Ready

Note that the support for DCE functions Data Carrier Detect and Ring Indicator are not provided. If these signals are required, their function can be emulated by using a general-purpose I/O signal and providing software support.

### 19.3.6.2 Flow Control

Flow control can be accomplished by either hardware or software. The following sections describe the different methods.

#### Hardware Flow Control (RTS/CTS)

Hardware flow control between two devices is accomplished by connecting the  $\overline{\text{UnRTS}}$  output to the Clear-To-Send input on the receiving device, and connecting the Request-To-Send output on the receiving device to the  $\overline{\text{UnCTS}}$  input.

The  $\overline{\text{UnCTS}}$  input controls the transmitter. The transmitter may only transmit data when the  $\overline{\text{UnCTS}}$  input is asserted. The  $\overline{\text{UnRTS}}$  output signal indicates the state of the receive FIFO.  $\overline{\text{UnCTS}}$  remains asserted until the preprogrammed watermark level is reached, indicating that the Receive FIFO has no space to store additional characters.

The **UARTCTL** register bits 15 (CTSEN) and 14 (RTSEN) specify the flow control mode as shown in Table 19-2 on page 1279.

**Table 19-2. Flow Control Mode**

| CTSEN | RTSEN | Description                            |
|-------|-------|--|
| 1     | 1     | RTS and CTS flow control enabled       |
| 1     | 0     | Only CTS flow control enabled          |
| 0     | 1     | Only RTS flow control enabled          |
| 0     | 0     | Both RTS and CTS flow control disabled |

Note that when RTSEN is 1, software cannot modify the  $\overline{\text{UnRTS}}$  output value through the **UARTCTL** register Request to Send (RTS) bit, and the status of the RTS bit should be ignored.

#### Software Flow Control (Modem Status Interrupts)

Software flow control between two devices is accomplished by using interrupts to indicate the status of the UART. Interrupts may be generated for the  $\overline{\text{UnDSR}}$ ,  $\overline{\text{UnDCD}}$ ,  $\overline{\text{UnCTS}}$ , and  $\overline{\text{UnRI}}$  signals using bits 3:0 of the **UARTIM** register, respectively. The raw and masked interrupt status may be checked using the **UARTRIS** and **UARTMIS** register. These interrupts may be cleared using the **UARTICR** register.

### 19.3.7 9-Bit UART Mode

The UART provides a 9-bit mode that is enabled with the 9BITEN bit in the **UART9BITADDR** register. This feature is useful in a multi-drop configuration of the UART where a single master connected to multiple slaves can communicate with a particular slave through its address or set of addresses along with a qualifier for an address byte. All the slaves check for the address qualifier in the place of the parity bit and, if set, then compare the byte received with the preprogrammed address. If the address matches, then it receives or sends further data. If the address does not match, it drops the address byte and any subsequent data bytes. If the UART is in 9-bit mode, then the receiver operates with no parity mode. The address can be predefined to match with the received byte and it can be configured with the **UART9BITADDR** register. The matching can be extended to a set of addresses using the address mask in the **UART9BITAMASK** register. By default, the **UART9BITAMASK** is 0xFF, meaning that only the specified address is matched.

When not finding a match, the rest of the data bytes with the 9th bit cleared are dropped. If a match is found, then an interrupt is generated to the NVIC for further action. The subsequent data bytes with the cleared 9th bit are stored in the FIFO. Software can mask this interrupt in case  $\mu$ DMA and/or FIFO operations are enabled for this instance and processor intervention is not required. All the

send transactions with 9-bit mode are data bytes and the 9th bit is cleared. Software can override the 9th bit to be set (to indicate address) by overriding the parity settings to sticky parity with odd parity enabled for a particular byte. To match the transmission time with correct parity settings, the address byte can be transmitted as a single then a burst transfer. The Transmit FIFO does not hold the address/data bit, hence software should take care of enabling the address bit appropriately.

### 19.3.8 FIFO Operation

The UART has two 16x8 FIFOs; one for transmit and one for receive. Both FIFOs are accessed via the **UART Data (UARTDR)** register (see page 1286). Read operations of the **UARTDR** register return a 12-bit value consisting of 8 data bits and 4 error flags while write operations place 8-bit data in the transmit FIFO.

Out of reset, both FIFOs are disabled and act as 1-byte-deep holding registers. The FIFOs are enabled by setting the `FEN` bit in **UARTLCRH** (page 1297).

FIFO status can be monitored via the **UART Flag (UARTFR)** register (see page 1291) and the **UART Receive Status (UARTSR)** register. Hardware monitors empty, full and overrun conditions. The **UARTFR** register contains empty and full flags (`TXFE`, `TXFF`, `RXFE`, and `RXFF` bits), and the **UARTSR** register shows overrun status via the `OE` bit. If the FIFOs are disabled, the empty and full flags are set according to the status of the 1-byte-deep holding registers.

The trigger points at which the FIFOs generate interrupts is controlled via the **UART Interrupt FIFO Level Select (UARTIFLS)** register (see page 1303). Both FIFOs can be individually configured to trigger interrupts at different levels. Available configurations include  $\frac{1}{8}$ ,  $\frac{1}{4}$ ,  $\frac{1}{2}$ ,  $\frac{3}{4}$ , and  $\frac{7}{8}$ . For example, if the  $\frac{1}{4}$  option is selected for the receive FIFO, the UART generates a receive interrupt after 4 data bytes are received. Out of reset, both FIFOs are configured to trigger an interrupt at the  $\frac{1}{2}$  mark.

### 19.3.9 Interrupts

The UART can generate interrupts when the following conditions are observed:

- Overrun Error
- Break Error
- Parity Error
- Framing Error
- Receive Timeout
- Transmit (when condition defined in the `TXIFLSEL` bit in the **UARTIFLS** register is met, or if the `EOT` bit in **UARTCTL** is set, when the last bit of all transmitted data leaves the serializer)
- Receive (when condition defined in the `RXIFLSEL` bit in the **UARTIFLS** register is met)

All of the interrupt events are ORed together before being sent to the interrupt controller, so the UART can only generate a single interrupt request to the controller at any given time. Software can service multiple interrupt events in a single interrupt service routine by reading the **UART Masked Interrupt Status (UARTMIS)** register (see page 1313).

The interrupt events that can trigger a controller-level interrupt are defined in the **UART Interrupt Mask (UARTIM)** register (see page 1305) by setting the corresponding `IM` bits. If interrupts are not used, the raw interrupt status is visible via the **UART Raw Interrupt Status (UARTRIS)** register (see page 1309).

**Note:** For receive timeout, the `RTIM` bit in the **UARTIM** register must be set to see the `RTMIS` and `RTRIS` status in the **UARTMIS** and **UARTRIS** registers.

Interrupts are always cleared (for both the **UARTMIS** and **UARTRIS** registers) by writing a 1 to the corresponding bit in the **UART Interrupt Clear (UARTICR)** register (see page 1317).

The receive timeout interrupt is asserted when the receive FIFO is not empty, and no further data is received over a 32-bit period when the `HSE` bit is clear or over a 64-bit period when the `HSE` bit is set. The receive timeout interrupt is cleared either when the FIFO becomes empty through reading all the data (or by reading the holding register), or when a 1 is written to the corresponding bit in the **UARTICR** register.

The receive interrupt changes state when one of the following events occurs:

- If the FIFOs are enabled and the receive FIFO reaches the programmed trigger level, the `RXRIS` bit is set. The receive interrupt is cleared by reading data from the receive FIFO until it becomes less than the trigger level, or by clearing the interrupt by writing a 1 to the `RXIC` bit.
- If the FIFOs are disabled (have a depth of one location) and data is received thereby filling the location, the `RXRIS` bit is set. The receive interrupt is cleared by performing a single read of the receive FIFO, or by clearing the interrupt by writing a 1 to the `RXIC` bit.

The transmit interrupt changes state when one of the following events occurs:

- If the FIFOs are enabled and the transmit FIFO progresses through the programmed trigger level, the `TXRIS` bit is set. The transmit interrupt is based on a transition through level, therefore the FIFO must be written past the programmed trigger level otherwise no further transmit interrupts will be generated. The transmit interrupt is cleared by writing data to the transmit FIFO until it becomes greater than the trigger level, or by clearing the interrupt by writing a 1 to the `TXIC` bit.
- If the FIFOs are disabled (have a depth of one location) and there is no data present in the transmitters single location, the `TXRIS` bit is set. It is cleared by performing a single write to the transmit FIFO, or by clearing the interrupt by writing a 1 to the `TXIC` bit.

### 19.3.10 Loopback Operation

The UART can be placed into an internal loopback mode for diagnostic or debug work by setting the `LBE` bit in the **UARTCTL** register (see page 1299). In loopback mode, data transmitted on the `UnTx` output is received on the `UnRx` input. Note that the `LBE` bit should be set before the UART is enabled.

### 19.3.11 DMA Operation

The UART provides an interface to the  $\mu$ DMA controller with separate channels for transmit and receive. The DMA operation of the UART is enabled through the **UART DMA Control (UARTDMACTL)** register. When DMA operation is enabled, the UART asserts a DMA request on the receive or transmit channel when the associated FIFO can transfer data. For the receive channel, a single transfer request is asserted whenever any data is in the receive FIFO. A burst transfer request is asserted whenever the amount of data in the receive FIFO is at or above the FIFO trigger level configured in the **UARTIFLS** register. For the transmit channel, a single transfer request is asserted whenever there is at least one empty location in the transmit FIFO. The burst request is asserted whenever the transmit FIFO contains fewer characters than the FIFO trigger level. The single and burst DMA transfer requests are handled automatically by the  $\mu$ DMA controller depending on how the DMA channel is configured.

To enable DMA operation for the receive channel, set the `RXDMAE` bit of the **DMA Control (UARTDMACTL)** register. To enable DMA operation for the transmit channel, set the `TXDMAE` bit of the **UARTDMACTL** register. The UART can also be configured to stop using DMA for the receive channel if a receive error occurs. If the `DMAERR` bit of the **UARTDMACR** register is set and a receive error occurs, the DMA receive requests are automatically disabled. This error condition can be cleared by clearing the appropriate UART error interrupt.

When the  $\mu$ DMA is finished transferring data to the TX FIFO or from the RX FIFO, a `dma_done` signal is sent to the UART to indicate completion. The `dma_done` status is indicated through the `DMATXRIS` and `DMARXIS` bits of the **UARTRIS** register. An interrupt can be generated from these status bits by setting the `DMATXIM` and/or `DMARXIM` bits in the **UARTIM** register.

**Note:** The `DMATXRIS` bit can be used to indicate the  $\mu$ DMA's completion of data transfer to the TX FIFO. To indicate transfer completion from the UART's serializer, the end-of-transmission bit (`EOT` bit) should be enabled in the **UARTCTL** register. An interrupt can be generated on an end-of-transmission completion by setting the `EOTIM` bit of the **UARTIM** register.

See "Micro Direct Memory Access ( $\mu$ DMA)" on page 667 for more details about programming the  $\mu$ DMA controller.

## 19.4 Initialization and Configuration

To enable and initialize the UART, the following steps are necessary:

1. Enable the UART module using the **RCGCUART** register (see page 386).
2. Enable the clock to the appropriate GPIO module via the **RCGCGPIO** register (see page 380). To find out which GPIO port to enable, refer to Table 28-5 on page 1693.
3. Set the GPIO `AFSEL` bits for the appropriate pins (see page 762). To determine which GPIOs to configure, see Table 28-4 on page 1680.
4. Configure the GPIO current level and/or slew rate as specified for the mode selected (see page 764 and page 772).
5. Configure the `PMCn` fields in the **GPIOPCTL** register to assign the UART signals to the appropriate pins (see page 779 and Table 28-5 on page 1693).

To use the UART, the peripheral clock must be enabled by setting the appropriate bit in the **RCGCUART** register (page 386). In addition, the clock to the appropriate GPIO module must be enabled via the **RCGCGPIO** register (page 380) in the System Control module. To find out which GPIO port to enable, refer to Table 28-5 on page 1693.

This section discusses the steps that are required to use a UART module. For this example, the UART clock is assumed to be 20 MHz, and the desired UART configuration is:

- 115200 baud rate
- Data length of 8 bits
- One stop bit
- No parity
- FIFOs disabled

- No interrupts

The first thing to consider when programming the UART is the baud-rate divisor (BRD), because the **UARTIBRD** and **UARTFBRD** registers must be written before the **UARTLCRH** register. Using the equation described in “Baud-Rate Generation” on page 1275, the BRD can be calculated:

$$\text{BRD} = 20,000,000 / (16 * 115,200) = 10.8507$$

which means that the **DIVINT** field of the **UARTIBRD** register (see page 1295) should be set to 10 decimal or 0xA. The value to be loaded into the **UARTFBRD** register (see page 1296) is calculated by the equation:

$$\text{UARTFBRD}[\text{DIVFRAC}] = \text{integer}(0.8507 * 64 + 0.5) = 54$$

With the BRD values in hand, the UART configuration is written to the module in the following order:

1. Disable the UART by clearing the **UARTEN** bit in the **UARTCTL** register.
2. Write the integer portion of the BRD to the **UARTIBRD** register.
3. Write the fractional portion of the BRD to the **UARTFBRD** register.
4. Write the desired serial parameters to the **UARTLCRH** register (in this case, a value of 0x0000.0060).
5. Configure the UART clock source by writing to the **UARTCC** register.
6. Optionally, configure the  $\mu$ DMA channel (see “Micro Direct Memory Access ( $\mu$ DMA)” on page 667) and enable the DMA option(s) in the **UARTDMACTL** register.
7. Enable the UART by setting the **UARTEN** bit in the **UARTCTL** register.

## 19.5 Register Map

Table 19-3 on page 1284 lists the UART registers. The offset listed is a hexadecimal increment to the register's address, relative to that UART's base address:

- UART0: 0x4000.C000
- UART1: 0x4000.D000
- UART2: 0x4000.E000
- UART3: 0x4000.F000
- UART4: 0x4001.0000
- UART5: 0x4001.1000
- UART6: 0x4001.2000
- UART7: 0x4001.3000

The UART module clock must be enabled before the registers can be programmed (see page 386). There must be a delay of 3 system clocks after the UART module clock is enabled before any UART module registers are accessed.

The UART must be disabled (see the **UARTEN** bit in the **UARTCTL** register on page 1299) before any of the control registers are reprogrammed. When the UART is disabled during a TX or RX operation, the current transaction is completed prior to the UART stopping.

**Note:** Registers that contain bits for modem control or status only apply to the following UARTs:

- UART0 (modem flow control and modem status)

- UART1 (modem flow control and modem status)
- UART2 (modem flow control)
- UART3 (modem flow control)
- UART4 (modem flow control)

**Table 19-3. UART Register Map**

| Offset | Name           | Type | Reset       | Description                       | See page |

## 19.6 Register Descriptions

The remainder of this section lists and describes the UART registers, in numerical order by address offset.

## Register 1: UART Data (UARTDR), offset 0x000

**Important:** This register is read-sensitive. See the register description for details.

This register is the data register (the interface to the FIFOs).

For transmitted data, if the FIFO is enabled, data written to this location is pushed onto the transmit FIFO. If the FIFO is disabled, data is stored in the transmitter holding register (the bottom word of the transmit FIFO). A write to this register initiates a transmission from the UART.

For received data, if the FIFO is enabled, the data byte and the 4-bit status (break, frame, parity, and overrun) is pushed onto the 12-bit wide receive FIFO. If the FIFO is disabled, the data byte and status are stored in the receiving holding register (the bottom word of the receive FIFO). The received data can be retrieved by reading this register.

### UART Data (UARTDR)

UART0 base: 0x4000.C000  
 UART1 base: 0x4000.D000  
 UART2 base: 0x4000.E000  
 UART3 base: 0x4000.F000  
 UART4 base: 0x4001.0000  
 UART5 base: 0x4001.1000  
 UART6 base: 0x4001.2000  
 UART7 base: 0x4001.3000  
 Offset 0x000  
 Type RW, reset 0x0000.0000

| Bit/Field | Name     | Type | Reset    | Description   |
|-----------|----------|------|----------|---|
| 31:12     | reserved | RO   | 0x0000.0 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 11        | OE       | RO   | 0        | UART Overrun Error  |
|           |          |      |          | Value Description   |
|           |          |      |          | 0 No data has been lost due to a FIFO overrun.  |
|           |          |      |          | 1 New data was received when the FIFO was full, resulting in data loss.   |

| Bit/Field | Name | Type | Reset | Description  |
|-----------|------|------|-------|--|
| 10        | BE   | RO   | 0     | <p>UART Break Error</p> <p>Value Description</p> <p>0 No break condition has occurred</p> <p>1 A break condition has been detected, indicating that the receive data input was held Low for longer than a full-word transmission time (defined as start, data, parity, and stop bits).</p> <p>In FIFO mode, this error is associated with the character at the top of the FIFO. When a break occurs, only one 0 character is loaded into the FIFO. The next character is only enabled after the received data input goes to a 1 (marking state), and the next valid start bit is received.</p> |
| 9         | PE   | RO   | 0     | <p>UART Parity Error</p> <p>Value Description</p> <p>0 No parity error has occurred</p> <p>1 The parity of the received data character does not match the parity defined by bits 2 and 7 of the <b>UARTLCRH</b> register.</p> <p>In FIFO mode, this error is associated with the character at the top of the FIFO.</p>   |
| 8         | FE   | RO   | 0     | <p>UART Framing Error</p> <p>Value Description</p> <p>0 No framing error has occurred</p> <p>1 The received character does not have a valid stop bit (a valid stop bit is 1).</p>  |
| 7:0       | DATA | RW   | 0x00  | <p>Data Transmitted or Received</p> <p>Data that is to be transmitted via the UART is written to this field.</p> <p>When read, this field contains the data that was received by the UART.</p>   |

## Register 2: UART Receive Status/Error Clear (UARTRSR/UARTECR), offset 0x004

The **UARTRSR/UARTECR** register is the receive status register/error clear register.

In addition to the **UARTDR** register, receive status can also be read from the **UARTRSR** register. If the status is read from this register, then the status information corresponds to the entry read from **UARTDR** prior to reading **UARTRSR**. The status information for overrun is set immediately when an overrun condition occurs.

The **UARTRSR** register cannot be written.

A write of any value to the **UARTECR** register clears the framing, parity, break, and overrun errors. All the bits are cleared on reset.

### Read-Only Status Register

#### UART Receive Status/Error Clear (UARTRSR/UARTECR)

UART0 base: 0x4000.C000  
 UART1 base: 0x4000.D000

| Bit/Field | Name     | Type | Reset      | Description   |
|-----------|----------|------|------------|---|
| 31:4      | reserved | RO   | 0x0000.000 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |

|   |    |    |   |                    |
|---|----|----|---|--------------------|
| 3 | OE | RO | 0 | UART Overrun Error |
|---|----|----|---|--------------------|

#### Value Description

| Value | Description   |
|-------|---|
| 0     | No data has been lost due to a FIFO overrun.                          |
| 1     | New data was received when the FIFO was full, resulting in data loss. |

This bit is cleared by a write to **UARTECR**.

The FIFO contents remain valid because no further data is written when the FIFO is full, only the contents of the shift register are overwritten. The CPU must read the data in order to empty the FIFO.

| Bit/Field | Name | Type | Reset | Description  |
|-----------|------|------|-------|--|
| 2         | BE   | RO   | 0     | <p>UART Break Error</p> <p>Value Description</p> <p>0 No break condition has occurred</p> <p>1 A break condition has been detected, indicating that the receive data input was held Low for longer than a full-word transmission time (defined as start, data, parity, and stop bits).</p> <p>This bit is cleared to 0 by a write to <b>UARTECR</b>.</p> <p>In FIFO mode, this error is associated with the character at the top of the FIFO. When a break occurs, only one 0 character is loaded into the FIFO. The next character is only enabled after the receive data input goes to a 1 (marking state) and the next valid start bit is received.</p> |

|-----------|----------|------|-----------|---|
| 31:8      | reserved | WO   | 0x0000.00 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 7:0       | DATA     | WO   | 0x00      | Error Clear<br>A write to this register of any data clears the framing, parity, break, and overrun flags.   |

### Register 3: UART Flag (UARTFR), offset 0x018

The **UARTFR** register is the flag register. After reset, the **TXFF**, **RXFF**, and **BUSY** bits are 0, and **TXFE** and **RXFE** bits are 1.

**Note:** Registers that contain bits for modem control or status only apply to the following UARTs:

- UART0 (modem flow control and modem status)
- UART1 (modem flow control and modem status)
- UART2 (modem flow control)
- UART3 (modem flow control)
- UART4 (modem flow control)

### Register 4: UART IrDA Low-Power Register (UARTILPR), offset 0x020

The **UARTILPR** register stores the 8-bit low-power counter divisor value used to derive the low-power SIR pulse width clock by dividing down the system clock (SysClk). All the bits are cleared when reset.

The internal  $F_{IrLPBaud16}$  clock is generated by dividing down SysClk according to the low-power divisor value written to **UARTILPR**. The duration of SIR pulses generated when low-power mode is enabled is three times the period of the  $F_{IrLPBaud16}$  clock. The low-power divisor value is calculated as follows:

$$ILPDVSR = SysClk / F_{IrLPBaud16}$$

where  $F_{IrLPBaud16}$  is nominally 1.8432 MHz.

Because the  $F_{IrLPBaud16}$  clock is used to sample transmitted data irrespective of mode, the **ILPDVSR** field must be programmed in both low power and normal mode, such that  $1.42 \text{ MHz} < F_{IrLPBaud16} < 2.12 \text{ MHz}$ , resulting in a low-power pulse duration of 1.41–2.11  $\mu\text{s}$  (three times the period of  $F_{IrLPBaud16}$ ). The minimum frequency of  $F_{IrLPBaud16}$  ensures that pulses less than one period of  $F_{IrLPBaud16}$  are rejected, but pulses greater than 1.4  $\mu\text{s}$  are accepted as valid pulses.

**Note:** Zero is an illegal value. Programming a zero value results in no  $F_{IrLPBaud16}$  pulses being generated.

#### UART IrDA Low-Power Register (UARTILPR)

UART0 base: 0x4000.C000

**Register 5: UART Integer Baud-Rate Divisor (UARTIBRD), offset 0x024**

The **UARTIBRD** register is the integer part of the baud-rate divisor value. All the bits are cleared on reset. The minimum possible divide ratio is 1 (when **UARTIBRD**=0), in which case the **UARTFBRD** register is ignored. When changing the **UARTIBRD** register, the new value does not take effect until transmission/reception of the current character is complete. Any changes to the baud-rate divisor must be followed by a write to the **UARTLCRH** register. See “Baud-Rate Generation” on page 1275 for configuration details.

## Register 7: UART Line Control (UARTLCRH), offset 0x02C

The **UARTLCRH** register is the line control register. Serial parameters such as data length, parity, and stop bit selection are implemented in this register.

When updating the baud-rate divisor (**UARTIBRD** and/or **UARTIFRD**), the **UARTLCRH** register must also be written. The write strobe for the baud-rate divisor registers is tied to the **UARTLCRH** register.

For the proper execution of the break command, software must set this bit for at least two frames (character periods).</p>   |

**Register 8: UART Control (UARTCTL), offset 0x030**

The **UARTCTL** register is the control register. All the bits are cleared on reset except for the Transmit Enable (**TXE**) and Receive Enable (**RXE**) bits, which are set.

To enable the UART module, the **UARTEN** bit must be set. If software requires a configuration change in the module, the **UARTEN** bit must be cleared before the configuration changes are written. If the UART is disabled during a transmit or receive operation, the current transaction is completed prior to the UART stopping.

**Note:** Registers that contain bits for modem control or status only apply to the following UARTs:

- UART0 (modem flow control and modem status)
- UART1 (modem flow control and modem status)
- UART2 (modem flow control)
- UART3 (modem flow control)
- UART4 (modem flow control)

**Note:** The **UARTCTL** register should not be changed while the UART is enabled or else the results are unpredictable. The following sequence is recommended for making changes to the **UARTCTL** register.

1. Disable the UART.
2. Wait for the end of transmission or reception of the current character.
3. Flush the transmit FIFO by clearing bit 4 (**FEN**) in the line control register (**UARTLCRH**).
4. Reprogram the control register.
5. Enable the UART.

**UART Control (UARTCTL)**

**Register 9: UART Interrupt FIFO Level Select (UARTIFLS), offset 0x034**

The **UARTIFLS** register is the interrupt FIFO level select register. You can use this register to define the FIFO level at which the **TXRIS** and **RXRIS** bits in the **UARTRIS** register are triggered.

The interrupts are generated based on a transition through a level rather than being based on the level. That is, the interrupts are generated when the fill level progresses through the trigger level. For example, if the receive trigger level is set to the half-way mark, the interrupt is triggered as the module is receiving the 9th character.

Out of reset, the **TXIFLSEL** and **RXIFLSEL** bits are configured so that the FIFOs trigger an interrupt at the half-way mark.

**UART Interrupt FIFO Level Select (UARTIFLS)**

| 0x4     | TX FIFO $\leq$ $\frac{1}{8}$ empty           |
| 0x5-0x7 | Reserved                                     |

**Note:** If the `EOT` bit in `UARTCTL` is set (see page 1299), the transmit interrupt is generated once the FIFO is completely empty and all data including stop bits have left the transmit serializer. In this case, the setting of `TXIFLSEL` is ignored.

## Register 10: UART Interrupt Mask (UARTIM), offset 0x038

The **UARTIM** register is the interrupt mask set/clear register.

On a read, this register gives the current value of the mask on the relevant interrupt. Setting a bit allows the corresponding raw interrupt signal to be routed to the interrupt controller. Clearing a bit prevents the raw interrupt signal from being sent to the interrupt controller.

**Note:** Registers that contain bits for modem control or status only apply to the following UARTs:

- UART0 (modem flow control and modem status)
- UART1 (modem flow control and modem status)
- UART2 (modem flow control)
- UART3 (modem flow control)
- UART4 (modem flow control)

**Register 13: UART Interrupt Clear (UARTICR), offset 0x044**

The **UARTICR** register is the interrupt clear register. On a write of 1, the corresponding interrupt (both raw interrupt and masked interrupt, if enabled) is cleared. A write of 0 has no effect.

Note that bits [3:0] are only implemented on UART1. These bits are reserved on UART0 and UART2.

### Register 15: UART 9-Bit Self Address (UART9BITADDR), offset 0x0A4

The **UART9BITADDR** register is used to write the specific address that should be matched with the receiving byte when the 9-bit Address Mask (**UART9BITAMASK**) is set to 0xFF. This register is used in conjunction with **UART9BITAMASK** to form a match for address-byte received.

## Register 17: UART Peripheral Properties (UARTPP), offset 0xFC0

The **UARTPP** register provides information regarding the properties of the UART module.

### UART Peripheral Properties (UARTPP)

UART0 base: 0x4000.C000  
 UART1 base: 0x4000.D000  
 UART2 base: 0x4000.E000  
 UART3 base: 0x4000.F000  
 UART4 base: 0x4001.0000  
 UART5 base: 0x4001.1000  
 UART6 base: 0x4001.2000  
 UART7 base: 0x4001.3000  
 Offset 0xFC0  
 Type RO, reset 0x0000.000F

| Bit/Field | Name     | Type | Reset | Description   |
|-----------|----------|------|-------|---|
| 31:4      | reserved | RO   | 0x0   | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.   |
| 3         | MSE      | RO   | 0x1   | Modem Support Extended<br><br>Value Description<br>0 The UART module does not provide extended support for modem control.<br>1 The UART module provides extended support for modem control including <i>UARTnDTR</i> , <i>UARTnDSR</i> , <i>UARTnDCD</i> , and <i>UARTnRI</i> . |
| 2         | MS       | RO   | 0x1   | Modem Support<br><br>Value Description<br>0 The UART module does not provide support for modem control.<br>1 The UART module provides support for modem control including <i>UARTnRTS</i> and <i>UARTnCTS</i> .   |
| 1         | NB       | RO   | 0x1   | 9-Bit Support<br><br>Value Description<br>0 The UART module does not provide support for the transmission of 9-bit data for RS-485 support.<br>1 The UART module provides support for the transmission of 9-bit data for RS-485 support.  |

| Bit/Field | Name | Type | Reset | Description  |
|-----------|------|------|-------|--|
| 0         | SC   | RO   | 0x1   | Smart Card Support                                     |
|           |      |      |       | Value Description                                      |
|           |      |      |       | 0 The UART module does not provide smart card support. |
|           |      |      |       | 1 The UART module provides smart card support.         |

### Register 18: UART Clock Configuration (UARTCC), offset 0xFC8

The **UARTCC** register controls the baud clock source for the UART module. For more information, see the section called “Peripheral Clock Sources” on page 236.

**Note:** If the PIOSC is used for the UART baud clock, the system clock frequency must be at least 9 MHz in Run mode.

#### UART Clock Configuration (UARTCC)

UART0 base: 0x4000.C000  
 UART1 base: 0x4000.D000  
 UART2 base: 0x4000.E000  
 UART3 base: 0x4000.F000  
 UART4 base: 0x4001.0000  
 UART5 base: 0x4001.1000  
 UART6 base: 0x4001.2000  
 UART7 base: 0x4001.3000  
 Offset 0xFC8  
 Type RW, reset 0x0000.0000

| Bit/Field | Name  | Type | Reset      | Description   |       |             |     |   |         |          |     |  |         |          |
|-----------|---|------|------------|---|-------|-------------|-----|---|---------|----------|-----|--|---------|----------|

## 20 Quad Synchronous Serial Interface (QSSI)

The TM4C129CNCZAD microcontroller includes four Quad-Synchronous Serial Interface (QSSI) modules. All four of the modules support Advanced and Bi-SSI interfaces as well as a Quad-SSI enhancement to provide faster throughput of data. The QSSI module acts as a master or slave interface for synchronous serial communication with peripheral devices that have either Freescale SPI, or Texas Instruments synchronous serial interfaces. The QSSI performs serial-to-parallel conversion on data received from a peripheral device. The transmit and receive paths are buffered with internal, independent FIFO memories allowing up to eight 16-bit values in Legacy mode and 8-bit values in Advanced, Bi-, and Quad-modes. The CPU can access data in these FIFOs as well as the QSSI's control and status information. A  $\mu$ DMA interface is also provided to allow the transmit and receive FIFOs to be programmed as source/destination addresses in the  $\mu$ DMA module.

The TM4C129CNCZAD QSSI modules have the following features:

- Four QSSI channels with Advanced, Bi- and Quad-SSI functionality
- Programmable interface operation for Freescale SPI or Texas Instruments synchronous serial interfaces in Legacy Mode. Support for Freescale interface in Bi- and Quad-SSI mode.
- Master or slave operation
- Programmable clock bit rate and prescaler
- Separate transmit and receive FIFOs, each 16 bits wide and 8 locations deep
- Programmable data frame size from 4 to 16 bits
- Internal loopback test mode for diagnostic/debug testing
- Standard FIFO-based interrupts and End-of-Transmission interrupt
- Efficient transfers using Micro Direct Memory Access Controller ( $\mu$ DMA)
  - Separate channels for transmit and receive
  - Receive single request asserted when data is in the FIFO; burst request asserted when FIFO contains 4 entries
  - Transmit single request asserted when there is space in the FIFO; burst request asserted when four or more entries are available to be written in the FIFO
  - Maskable  $\mu$ DMA interrupts for receive and transmit complete
- Global Alternate Clock (ALTCLK) resource or System Clock (SYSCLK) can be used to generate baud clock.

### 20.1 Block Diagram

The following figure below shows a block diagram of an QSSI module with Advanced, Bi- and Quad-SSI.

Figure 20-1. QSSI Module with Advanced, Bi-SSI and Quad-SSI Support

## 20.2 Signal Description

The following table lists the external signals of the QSSI module and describes the function of each. The QSSI signals are alternate functions for some GPIO signals and default to be GPIO signals at reset. The "Pin Mux/Pin Assignment" column in the following table lists the possible GPIO pin placements for the QSSI signals. The **AFSEL** bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 762) should be set to choose the QSSI function. The number in

parentheses is the encoding that must be programmed into the  $PMC_n$  field in the **GPIO Port Control (GPIOPCTL)** register (page 779) to assign the QSSI signal to the specified GPIO port pin. For more information on configuring GPIOs, see “General-Purpose Input/Outputs (GPIOs)” on page 731. Note that for the QSSI module, when operating in Legacy Mode,  $SSI_nXDAT_0$  functions as  $SSI_nTX$  and  $SSI_nXDAT_1$  functions as  $SSI_nRX$ .

**Table 20-1. SSI Signals (212BGA)**

| Pin Name  | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type | Description   |

## 20.3 Functional Description

The QSSI performs serial-to-parallel conversion on data received from a peripheral device. The CPU accesses data, control, and status information. The transmit and receive paths are buffered with internal FIFO memories allowing up to eight 16-bit values to be stored independently in both transmit and receive modes. The QSSI also supports the  $\mu$ DMA interface. The transmit and receive FIFOs can be programmed as destination/source addresses in the  $\mu$ DMA module.  $\mu$ DMA operation is enabled by setting the appropriate bit(s) in the **SSIDMACTL** register (see page 1371).

### 20.3.1 Bit Rate Generation

The QSSI includes a programmable bit rate clock divider and prescaler to generate the serial output clock. Bit rates are supported to 2 MHz and higher, although maximum bit rate is determined by peripheral devices.

The serial bit rate is derived by dividing down the input clock (SysClk). The clock is first divided by an even prescale value **CPSDVSR** from 2 to 254, which is programmed in the **SSI Clock Prescale (SSICPSR)** register (see page 1363). The clock is further divided by a value from 1 to 256, which is  $1 + \text{SCR}$ , where **SCR** is the value programmed in the **SSI Control 0 (SSICR0)** register (see page 1356).

The frequency of the output clock **SSInClk** is defined by:

$$\text{SSInClk} = \text{SysClk} / (\text{CPSDVSR} * (1 + \text{SCR}))$$

**Note:** SYSClk or ALTCLK is used as the source for the **SSInClk** depending on how the **CS** field in the **SSI Clock Configuration (SSICC)** register is configured. For master legacy mode, the SYSClk or ALTCLK must be at least two times faster than the **SSInClk**, with the restriction that **SSInClk** cannot be faster than 60 MHz. For slave mode, SYSClk or ALTCLK must be at least 12 times faster than the **SSInClk**. In slave legacy mode, the maximum frequency of **SSInClk** is 10 MHz.

See "Synchronous Serial Interface (SSI)" on page 1754 to view legacy SSI and QSSI timing parameters.

### 20.3.2 FIFO Operation

#### 20.3.2.1 Transmit FIFO

The common transmit FIFO is a 16-bit wide, 8-locations deep, first-in, first-out memory buffer. The CPU writes data to the FIFO by writing the **SSI Data (SSIDR)** register (see page 1360), and data is stored in the FIFO until it is read out by the transmission logic.

When configured as a master or a slave, parallel data is written into the transmit FIFO prior to a legacy SSI serial conversion and transmission to the attached slave or master, respectively, through the **SSInDAT0/SSInTX** pin.

In slave mode, the legacy SSI transmits data each time the master initiates a transaction. If the transmit FIFO is empty and the master initiates, the slave transmits the 8th most recent value in the transmit FIFO. If less than 8 values have been written to the transmit FIFO since the SSI module clock was enabled using the **Rn** bit in the **RCGCSSI** register or if the QSSI is reset using the **SRSSI** register, then 0 is transmitted. Care should be taken to ensure that valid data is in the FIFO as needed. The QSSI can be configured to generate an interrupt or a  $\mu$ DMA request when the FIFO is empty.

**Note:** When operating in Legacy Mode, the QuadSSI's **SSInXDAT0** signal functions as **SSInTX**.

### 20.3.2.2 Receive FIFO

The common receive FIFO is a 16-bit wide, 8-locations deep, first-in, first-out memory buffer. Received data using the legacy serial interface is stored in the buffer until read out by the CPU, which accesses the read FIFO by reading the **SSIDR** register. If the receive FIFO is full when the master or slave receives new data, the data is held off until the receive FIFO has space.

The SSI only provides an SSIClk while transmitting data. When receiving data in master mode, a dummy write to the **SSIDR** register must be performed before any read so that the SSIClk can be properly received by the slave and allow data to be sent to the receive FIFO of the master.

When configured as a master or slave, serial data received through the SSInDAT1/SSInRX pin is registered prior to parallel loading into the attached slave or master receive FIFO, respectively.

**Note:** When operating in Legacy Mode, the QSSI's SSInXDAT1 signal functions as SSInRX.

### 20.3.3 Advanced, Bi- and Quad- SSI Function

Bi-SSI uses two data pins, SSInXDAT0 and SSInXDAT1, that can be configured to receive or transmit data. In Quad-SSI mode, SSInXDAT0, SSInXDAT1, SSInXDAT2 and SSInXDAT3 allow four bits of data to be received or transmitted at once. Note that in bi- and quad-SSI data transfers are only half-duplex.

By programming the **MODE** bits in the **SSICR1** register, Advanced, Bi- or Quad- SSI can be enabled. A direction bit, **DIR**, is provided to program the direction of operation during a Bi- or Quad SSI-transaction. Since Bi- and Quad-SSI cannot be full duplex, the **DIR** bit defines whether or not the RX FIFO is disabled. In Advanced operation, if the QSSI module TX (write) mode is enabled, the RX FIFO is automatically prevented from receiving any data. When Advanced SSI is in RX (read) mode, it operates as a full-duplex interface.

In Bi- and Quad-SSI mode, because only 8-bit data is allowed, the **DSS** bit field must be programmed to 0x7 in the **SSICR0** register before transferring data to the Rx and TX FIFOs. For a data transmit, the 8-bit data packet is placed in a TX FIFO entry bits [7:0] and the mode of operation is inserted in the three most significant bits of the TX FIFO entry. The mode of operation bits [15:13] in the TX FIFO are used by the QSSI module for configuring the data on the proper pins. The following modes that may be placed on bits [15:13] of the FIFO entry are:

- Bi-SSI mode (0x1)
- Quad-SSI mode (0x2)
- Advanced SSI mode (0x3)

When data is first written to the TX FIFO, a SSInFSS is asserted low indicating the start of a frame. At the end of transmission, bit 12 of the last data entry in the TX FIFO signifies whether a a frame is ending. When the **EOM** bit is 1 it indicates a End of Message (EOM or STOP frame) and SSInFSS is subsequently forced high. The **EOM** bit is cleared in the **SSICR1** register on the same clock that the write to TXFIFO is completed. An **EOM** bit value of 0 indicates no change in transmission. If TX FIFO is emptied and SSInFSS is still asserted low, it remains low but SSInCLK is not pulsed. Likewise, if SSInFSS is high when the TX FIFO is empty, it remains high.

During a Bi-SSI transmit frame, data is shifted out by two bits and placed on the corresponding two SSInDATn pins. For a Quad-SSI transmit frame data is shifted out by four bits and placed on the corresponding four SSInDATn pins.

In Bi-, Quad- and Advanced SSI, the lower byte of the Rx FIFO contains received data. The upper byte contains no valid information.

**Note:** While the master is in Bi- or Quad-SSI mode, if the `DSS` bit in the **SSICR0** register is not set to 0x7, the QSSI module reverts to Legacy mode and behavior is not guaranteed.

The **SSICR1** register bits `DIR` and `MODE` are used to program what operation is needed for the next data bytes that are being loaded into the FIFO. Table 20-2 on page 1342 shows available modes of operation:

**Table 20-2. QSSI Transaction Encodings**

| DIR | MODE | Operation   |
|-----|------|---|
| X   | 0x0  | SSI Legacy operation supporting 4 to 16 data bits                                     |
| 0   | 0x1  | Transmit (TX) Bi-SSI with 8-bits of packet data                                       |
| 0   | 0x2  | Transmit (TX) Quad-SSI with 8-bits of packet data                                     |
| 0   | 0x3  | Transmit (TX) Advanced SSI mode with 8-bits of packet data and write RX FIFO disabled |
| 1   | 0x1  | Receive (RX) Bi-SSI with 8-bits of packet data  |
| 1   | 0x2  | Receive (RX) Quad-SSI with 8-bits of packet data                                      |
| 1   | 0x3  | Full duplex Advance SSI with 8-bits of packet data                                    |

**Note:** `SPO = 0` and `SPH = 0` is the only frame structure allowed for Advanced, Bi- and Quad-mode.

Different transactions can follow one another in the FIFOs. The following transaction combinations are allowed:

- Legacy SSI mode (if configured for this mode, switching to any other alternate mode is not recommended)
- Advanced SSI mode followed by Bi-SSI mode
- Advanced SSI mode followed by Quad-SSI mode
- Advanced SSI mode followed by Bi-SSI mode followed by Advanced SSI mode
- Advanced SSI mode followed by Quad-SSI mode followed by Advanced SSI mode

Note that switching between Quad-SSI and Bi-SSI is not encouraged in a single transaction.

#### 20.3.4 SSInFSS Function

For enhanced modes of operation, the `SSInFSS` signal can be programmed to assert low at the start of each byte transfer for one clock or the entire frame. This is configured by programming the `FSSHLDFRM` bit in the **SSICR1** register. The `EOM` bit is also provided to signify end of frame transmission. This bit is embedded in the TXFIFO entry for use at the interface to deassert `SSInFSS` at the appropriate time. The `FSSHLDFRM` bit can also be used when operating in 8-bit Legacy SSI mode.

The functionality of the `FSSHLDFRM` bit for both Legacy SSI mode and the enhanced modes are as follows:

Table 20-3. SSInFss Functionality

| Mode                       | FSSHDFRM | Description   |
|----------------------------|----------|---|
| Legacy Mode                | 0        | For Freescale format, with <i>SPH</i> = 0, the <i>SSInFss</i> signal is asserted low between continuous transfers. For <i>SPH</i> = 1, the <i>SSInFss</i> signal is deasserted (high) between continuous transfers.<br>For TI format, the <i>SSInFss</i> signal is deasserted (high) after every data transfer. |
|                            | 1        | For Freescale format with any <i>SPH</i> value, the <i>SSInFss</i> signal is forced high between continuous transfers; it is asserted low when there is available data in the Tx FIFO; otherwise it is forced high to be ready for a new frame  |
| Advanced/Bi-/Quad-SSI Mode | 0        | <i>SSInFss</i> is asserted low after every byte of data   |
|                            | 1        | New data written to the TX FIFO notifies <i>SSInFss</i> to assert low until the Tx FIFO is empty.   |

### 20.3.5 High Speed Clock Operation

In master mode, QSSI module can enable a high speed clock by setting the *HSCLKEN* bit in the **SSI Control 1 (SSICR1)** register. In this mode of operation, *SSInCLK* from the QSSI master operation is reflected back as a loopback clock, *HSPEEDCLK*, to the QSSI module. This allows faster timing since the logic can be used to adjust clock to external data relationships. *HSPEEDCLK* captures RX data in a separate register. This allows the time between the clock as seen by a remote device and the internal clock to match more closely.

Receive data is captured in a separate register sampled on loop-back clock (*HSPEEDCLK*) and the RX FIFO write control registered on *HSPEEDCLK*. If the *HSCKEN* = 1, the corresponding shift register and FIFO write enable will be selected for use. This supports faster QSSI master speed.

**Note:** For proper functionality of high speed mode, the *HSCLKEN* bit in the **SSICR1** register should be set before any SSI data transfer or after applying a reset to the QSSI module. In addition, the *SSE* bit must be set to 0x1 before the *HSCLKEN* bit is set.

### 20.3.6 Interrupts

The QSSI can generate interrupts when the following conditions are observed:

- Transmit FIFO service (when the transmit FIFO is half full or less)
- Receive FIFO service (when the receive FIFO is half full or more)
- Receive FIFO time-out
- Receive FIFO overrun
- End of transmission
- Receive DMA transfer complete
- Transmit DMA transfer complete

All of the interrupt events are ORed together before being sent to the interrupt controller, so the QSSI generates a single interrupt request to the controller regardless of the number of active interrupts. Each of the seven individual maskable interrupts can be masked by clearing the appropriate bit in the **SSI Interrupt Mask (SSIIM)** register (see page 1364). Setting the appropriate mask bit enables the interrupt.

The individual outputs, along with a combined interrupt output, allow use of either a global interrupt service routine or modular device drivers to handle interrupts. The transmit and receive dynamic dataflow interrupts have been separated from the status interrupts so that data can be read or written in response to the FIFO trigger levels. The status of the individual interrupt sources can be read from the **SSI Raw Interrupt Status (SSIRIS)** and **SSI Masked Interrupt Status (SSIMIS)** registers (see page 1366 and page 1368, respectively).

The RX FIFO has an associated time-out counter which starts to down count at the same time the RX FIFO is flagged as not empty by the `RNE` bit in the **SSISR** register. The counter is reset any time a new or next byte is written to the RX FIFO, thus the counter will continue to count down to zero unless there is new activity. The time-out period is 32 periods based on the period of `SSInClk`. When the counter reaches zero, a time-out interrupt bit, `RTRIS`, is set in the **SSIRIS** register. The time-out interrupt can be cleared by writing a 1 to the `RTIC` bit of the **SSI Interrupt Clear (SSIC)** register or by emptying the RX FIFO. If the interrupt is cleared and there is residual data left in the RX FIFO or new data entries have been written, the timer count down initiates and the interrupt will be reasserted after 32 periods have been counted.

The End-of-Transmission (EOT) interrupt indicates that the data has been transmitted completely and is only valid for Master mode devices/operations. This interrupt can be used to indicate when it is safe to turn off the QSSI module clock or enter sleep mode. In addition, because transmitted data and received data complete at exactly the same time, the interrupt can also indicate that read data is ready immediately, without waiting for the receive FIFO time-out period to complete.

**Note:** In Freescale SPI mode only, a condition can be created where an EOT interrupt is generated for every byte transferred even if the FIFO is full. If the the  $\mu$ DMA has been configured to transfer data from this QSSI to a Master QSSI on the device using external loopback, an EOT interrupt is generated by the QSSI slave for every byte even if the FIFO is full.

### 20.3.7 Frame Formats

Each data frame is between 4 and 16 bits long in Legacy mode and 8-bits in Advanced/Bi-/Quad-SSI mode and is transmitted starting with the MSB. There are two basic frame types that can be selected by programming the `FRF` bit in the **SSICR0** register:

- Texas Instruments synchronous serial
- Freescale SPI

**Note:** Advanced, Bi- and Quad-SSI modules only supports Freescale mode when `SPH=0`; `SPO=0` and `DDS=0x8` in the **SSI Control 0 (SSICR0)** register.

For both formats, the serial clock (`SSInClk`) is held inactive while the QSSI is idle, and `SSInClk` transitions at the programmed frequency only during active transmission or reception of data. The idle state of `SSInClk` is utilized to provide a receive timeout indication that occurs when the receive FIFO still contains data after a timeout period.

For Freescale SPI frame format, the serial frame (`SSInFss`) pin is active Low, and is asserted (pulled down) during the entire transmission of the frame.

For Texas Instruments synchronous serial frame format, the `SSInFss` pin is pulsed for one serial clock period starting at its rising edge, prior to the transmission of each frame. For this frame format, both the QSSI and the off-chip slave device drive their output data on the rising edge of `SSInClk` and latch data from the other device on the falling edge.

The following table gives a synopsis of the features supported in each frame format when operating in Legacy Mode:

**Table 20-4. Legacy Mode TI, Freescale SPI Frame Format Features**

| Feature                            | TI Mode                  | Freescale SPI Mode   |
|------------------------------------|--------------------------|--|
| Frame Hold                         | Not Available            | Available  |
| High Speed (Master RX Only)        | Not Available            | Available  |
| SPO/SPH Configuration              | Not Available            | Available and can be used in combination with Frame Hold and High Speed Mode |
| Frequency (system clock : SSInCLK) | Master 1:2<br>Slave 1:12 | Master 1:2<br>Slave 1:12   |

For Advanced, Bi- and Quad-SSi modes using the Freescale SPI Format or the Bi- and Quad-SSi modes using the TI format, the following features are supported:

- Frame Hold
- High Speed (Master RX Only)
- SPO/SPH Configuration with  $SPO=0$  and  $SPH=0$  only allowed
- Frequency (system clock : SSInCLK):
  - Master 1:2
  - Slave 1:12

### 20.3.7.1 Texas Instruments Synchronous Serial Frame Format

Figure 20-2 on page 1345 shows the Texas Instruments synchronous serial frame format for a single transmitted frame.

**Figure 20-2. TI Synchronous Serial Frame Format (Single Transfer)**

In this mode, SSInClk and SSInFss are forced Low, and the transmit data line SSInDAT0/SSInTX is tristated whenever the QSSI is idle. Once the bottom entry of the transmit FIFO contains data, SSInFss is pulsed High for one SSInClk period. The value to be transmitted is also transferred from the transmit FIFO to the serial shift register of the transmit logic. On the next rising edge of SSInClk, the MSB of the 4 to 16-bit data frame is shifted out on the SSInDAT0/SSInTX pin. Likewise, the MSB of the received data is shifted onto the SSInDAT1/SSInRX pin by the off-chip serial slave device.

Both the QSSI and the off-chip serial slave device then clock each data bit into their serial shifter on each falling edge of SSInClk. The received data is transferred from the serial shifter to the receive FIFO on the first rising edge of SSInClk after the LSB has been latched.

Figure 20-3 on page 1346 shows the Texas Instruments synchronous serial frame format when back-to-back frames are transmitted.

**Figure 20-3. TI Synchronous Serial Frame Format (Continuous Transfer)**

### 20.3.7.2 Freescale SPI Frame Format

The Freescale SPI interface is a four-wire interface where the `SSInFss` signal behaves as a slave select. If operating in Legacy Mode and using the Freescale SPI Frame Format, the inactive state and phase of the `SSInClk` signal are programmable through the `SPO` and `SPH` bits in the `SSICR0` control register. If operating in Advanced/Bi-/Quad-SSI mode, the `SPO` and `SPH` bits must be programmed to 0.

#### **SPO Clock Polarity Bit**

When the `SPO` clock polarity control bit is clear, it produces a steady state Low value on the `SSInClk` pin. If the `SPO` bit is set, a steady state High value is placed on the `SSInClk` pin when data is not being transferred.

#### **SPH Phase Control Bit**

The `SPH` phase control bit selects the clock edge that captures data and allows it to change state. The state of this bit has the most impact on the first bit transmitted by either allowing or not allowing a clock transition before the first data capture edge. When the `SPH` phase control bit is clear, data is captured on the first clock edge transition. If the `SPH` bit is set, data is captured on the second clock edge transition.

### 20.3.7.3 Freescale SPI Frame Format with `SPO=0` and `SPH=0`

Single and continuous transmission signal sequences for Freescale SPI format with `SPO=0` and `SPH=0` are shown in Figure 20-4 on page 1347 and Figure 20-5 on page 1347.

**Note:** This is the only Freescale SPI frame format configuration that can be used when operating in Advanced/Bi-/Quad-SSI mode.

**Figure 20-4. Freescale SPI Format (Single Transfer) with SPO=0 and SPH=0**

**Note:** Q is undefined.

**Figure 20-5. Freescale SPI Format (Continuous Transfer) with SPO=0 and SPH=0**

In this configuration, during idle periods:

- SSInClk is forced Low
- SSInFss is forced High
- The transmit data line SSInDAT0/SSInTX is tristated
- When the QSSI is configured as a master, it enables the SSInClk pad
- When the QSSI is configured as a slave, it disables the SSInClk pad

If the QSSI is enabled and valid data is in the transmit FIFO, the start of transmission is signified by the SSInFss master signal being driven Low, causing slave data to be enabled onto the SSInDAT1/SSInRX input line of the master. The master SSInDAT0/SSInTX output pad is enabled.

One half SSInClk period later, valid master data is transferred to the SSInDAT0/SSInTX pin. Once both the master and slave data have been set, the SSInClk master clock pin goes High after one additional half SSInClk period.

The data is now captured on the rising and propagated on the falling edges of the SSInClk signal.

In the case of a single word transmission, after all bits of the data word have been transferred, the `SSInFss` line is returned to its idle High state one `SSInClk` period after the last bit has been captured.

However, in the case of continuous back-to-back transmissions, the `SSInFss` signal must be pulsed High between each data word transfer because the slave select pin freezes the data in its serial peripheral register and does not allow it to be altered if the `SPH` bit is clear. Therefore, the master device must raise the `SSInFss` pin of the slave device between each data transfer to enable the serial peripheral data write. On completion of the continuous transfer, the `SSInFss` pin is returned to its idle state one `SSInClk` period after the last bit has been captured.

#### 20.3.7.4 Freescale SPI Frame Format with `SPO=0` and `SPH=1`

The transfer signal sequence for Freescale SPI format with `SPO=0` and `SPH=1` is shown in Figure 20-6 on page 1348, which covers both single and continuous transfers.

**Note:** This Freescale SPI frame format configuration is only available when operating in Legacy SSI mode of operation.

**Figure 20-6. Freescale SPI Frame Format with `SPO=0` and `SPH=1`**

**Note:** Q is undefined.

In this configuration, during idle periods:

- `SSInClk` is forced Low
- `SSInFss` is forced High
- The transmit data line `SSInDAT0/SSInTX` is tristated
- When the QSSI is configured as a master, it enables the `SSInClk` pad
- When the QSSI is configured as a slave, it disables the `SSInClk` pad

If the QSSI is enabled and valid data is in the transmit FIFO, the start of transmission is signified by the `SSInFss` master signal being driven Low. The master `SSInDAT0/SSInTX` output is enabled. After an additional one-half `SSInClk` period, both master and slave valid data are enabled onto their respective transmission lines. At the same time, the `SSInClk` is enabled with a rising edge transition.

Data is then captured on the falling edges and propagated on the rising edges of the `SSInClk` signal.

In the case of a single word transfer, after all bits have been transferred, the  $SSInFss$  line is returned to its idle High state one  $SSInClk$  period after the last bit has been captured.

For continuous back-to-back transfers, the  $SSInFss$  pin is held Low between successive data words, and termination is the same as that of the single word transfer.

### 20.3.7.5 Freescale SPI Frame Format with $SPO=1$ and $SPH=0$

Single and continuous transmission signal sequences for Freescale SPI format with  $SPO=1$  and  $SPH=0$  are shown in Figure 20-7 on page 1349 and Figure 20-8 on page 1349.

**Note:** This Freescale SPI frame format configuration is only available when operating in Legacy SSI mode of operation.

**Figure 20-7. Freescale SPI Frame Format (Single Transfer) with  $SPO=1$  and  $SPH=0$**

**Note:** Q is undefined.

**Figure 20-8. Freescale SPI Frame Format (Continuous Transfer) with  $SPO=1$  and  $SPH=0$**

In this configuration, during idle periods:

- $SSInClk$  is forced High
- $SSInFss$  is forced High
- The transmit data line  $SSInDAT0/SSInTX$  is tristated
- When the QSSI is configured as a master, it enables the  $SSInClk$  pad
- When the QSSI is configured as a slave, it disables the  $SSInClk$  pad

If the QSSI is enabled and valid data is in the transmit FIFO, the start of transmission is signified by the *SSInFss* master signal being driven Low, causing slave data to be immediately transferred onto the *SSInDAT1/SSInRX* line of the master. The master *SSInDAT0/SSInTX* output pad is enabled.

One-half period later, valid master data is transferred to the *SSInDAT0/SSInTX* line. Once both the master and slave data have been set, the *SSInClk* master clock pin becomes Low after one additional half *SSInClk* period, meaning that data is captured on the falling edges and propagated on the rising edges of the *SSInClk* signal.

In the case of a single word transmission, after all bits of the data word are transferred, the *SSInFss* line is returned to its idle High state one *SSInClk* period after the last bit has been captured.

However, in the case of continuous back-to-back transmissions, the *SSInFss* signal must be pulsed High between each data word transfer because the slave select pin freezes the data in its serial peripheral register and does not allow it to be altered if the *SPH* bit is clear. Therefore, the master device must raise the *SSInFss* pin of the slave device between each data transfer to enable the serial peripheral data write. On completion of the continuous transfer, the *SSInFss* pin is returned to its idle state one *SSInClk* period after the last bit has been captured.

**20.3.7.6 Freescale SPI Frame Format with SPO=1 and SPH=1**

The transfer signal sequence for Freescale SPI format with *SPO=1* and *SPH=1* is shown in Figure 20-9 on page 1350, which covers both single and continuous transfers.

**Note:** This Freescale SPI frame format configuration is only available when operating in Legacy SSI mode of operation.

**Figure 20-9. Freescale SPI Frame Format with SPO=1 and SPH=1**

**Note:** Q is undefined.

In this configuration, during idle periods:

- *SSInClk* is forced High
- *SSInFss* is forced High
- The transmit data line *SSInDAT0/SSInTX* is tristated
- When the QSSI is configured as a master, it enables the *SSInClk* pad
- When the QSSI is configured as a slave, it disables the *SSInClk* pad

If the QSSI is enabled and valid data is in the transmit FIFO, the start of transmission is signified by the `SSInFss` master signal being driven Low. The master `SSInDAT0/SSInTX` output pad is enabled. After an additional one-half `SSInClk` period, both master and slave data are enabled onto their respective transmission lines. At the same time, `SSInClk` is enabled with a falling edge transition. Data is then captured on the rising edges and propagated on the falling edges of the `SSInClk` signal.

After all bits have been transferred, in the case of a single word transmission, the `SSInFss` line is returned to its idle high state one `SSInClk` period after the last bit has been captured.

For continuous back-to-back transmissions, the `SSInFss` pin remains in its active Low state until the final bit of the last word has been captured and then returns to its idle state as described above.

For continuous back-to-back transfers, the `SSInFss` pin is held Low between successive data words and termination is the same as that of the single word transfer.

### 20.3.8 DMA Operation

The QSSI peripheral provides an interface to the  $\mu$ DMA controller with separate channels for transmit and receive. The  $\mu$ DMA operation of the QSSI is enabled through the **SSI DMA Control (SSIDMACTL)** register. When  $\mu$ DMA operation is enabled, the QSSI asserts a  $\mu$ DMA request on the receive or transmit channel when the associated FIFO can transfer data.

For the receive channel, a single transfer request is asserted whenever any data is in the receive FIFO. A burst transfer request is asserted whenever the amount of data in the receive FIFO is 4 or more items. For the transmit channel, a single transfer request is asserted whenever at least one empty location is in the transmit FIFO. The burst request is asserted whenever the transmit FIFO has 4 or more empty slots. The single and burst  $\mu$ DMA transfer requests are handled automatically by the  $\mu$ DMA controller depending how the  $\mu$ DMA channel is configured.

To enable  $\mu$ DMA operation for the receive channel, the `RXDMAE` bit of the **DMA Control (SSIDMACTL)** register should be set after configuring the  $\mu$ DMA. To enable  $\mu$ DMA operation for the transmit channel, the `TXDMAE` bit of **SSIDMACTL** should be set after configuring the  $\mu$ DMA.

If the  $\mu$ DMA is enabled and has completed a data transfer from the Tx FIFO, the `DMATXRIS` bit is set in the **SSIRIS** register and cannot be cleared by setting the `DMATXIC` bit in the **SSI Interrupt Clear (SSIICR)** register. In the DMA Completion Interrupt Service Routine, software must disable the  $\mu$ DMA transmit enable to the SSI by clearing the `TXDMAE` bit in the **QSSI DMA Control (SSIDMACTL)** register and then setting the `DMATXIC` bit in the **SSIICR** register. This clears the DMA completion interrupt. When the  $\mu$ DMA is needed to transmit more data, the `TXDMAE` bit must be set (enabled) again.

If a data transfer by the  $\mu$ DMA from the Rx FIFO completes, the `DMARXRIS` bit is set. The `EOT` bit in the **SSIRIS** register is also provided to indicate when the Tx FIFO is empty and the last bit has been transmitted out of the serializer.

**Note:** Wait states are inserted at every byte transfer when using Bi- or Quad-SSI modes as a master with the  $\mu$ DMA at `SSICLK` frequencies greater than 1/6 of the system clock. These wait states are because of arbitration stall cycles from the  $\mu$ DMA accesses to SRAM and increased output throughput from the SSI.

See “Micro Direct Memory Access ( $\mu$ DMA)” on page 667 for more details about programming the  $\mu$ DMA controller.

## 20.4 Initialization and Configuration

To enable and initialize the QSSI, the following steps are necessary:

1. Enable the QSSI module using the **RCGCSSI** register (see page 388).
2. Enable the clock to the appropriate GPIO module via the **RCGCGPIO** register (see page 380). To find out which GPIO port to enable, refer to Table 28-5 on page 1693.
3. Set the GPIO **AFSEL** bits for the appropriate pins (see page 762). To determine which GPIOs to configure, see Table 28-4 on page 1680.
4. Configure the **PMCn** fields in the **GPIOPCTL** register to assign the QSSI signals to the appropriate pins. See page 779 and Table 28-5 on page 1693.
5. Program the **GPIODEN** register to enable the pin's digital function. In addition, the drive strength, drain select and pull-up/pull-down functions must be configured. Refer to “General-Purpose Input/Outputs (GPIOs)” on page 731 for more information.

**Note:** Pull-ups can be used to avoid unnecessary toggles on the QSSI pins, which can take the slave to a wrong state. In addition, if the **SSIClk** signal is programmed to steady state High through the **SPO** bit in the **SSICR0** register, then software must also configure the GPIO port pin corresponding to the **SSInClk** signal as a pull-up in the **GPIO Pull-Up Select (GPIOPUR)** register.

For each of the frame formats, the QSSI is configured using the following steps:

1. If initializing out of reset, ensure that the **SSE** bit in the **SSICR1** register is clear before making any configuration changes. Otherwise, configuration changes for Advanced SSI can be made while the **SSE** bit is set.
2. Select whether the QSSI is a master or slave:
  - a. For master operations, set the **SSICR1** register to 0x0000.0000.
  - b. For slave mode (output enabled), set the **SSICR1** register to 0x0000.0004.
  - c. For slave mode (output disabled), set the **SSICR1** register to 0x0000.000C.
3. Configure the QSSI clock source by writing to the **SSICC** register.
4. Configure the clock prescale divisor by writing the **SSICPSR** register.
5. Write the **SSICR0** register with the following configuration:
  - Serial clock rate (**SCR**)
  - Desired clock phase/polarity, if using Freescale SPI mode (**SPH** and **SPO**)
  - The protocol mode: Freescale SPI or TI SSF
  - The data size (**DSS**)
6. Optionally, configure the SSI module for  $\mu$ DMA use with the following steps:
  - a. Configure a  $\mu$ DMA for SSI use. See “Micro Direct Memory Access ( $\mu$ DMA)” on page 667 for more information.
  - b. Enable the SSI Module's TX FIFO or RX FIFO by setting the **TXDMAE** or **RXDMAE** bit in the **SSIDMACTL** register.

- c. Optionally, enable the  $\mu$ DMA completion interrupt by setting the `DMATXIM` or `DMARXIM` bit in the **SSIM** register.

**Note:** For a TX DMA completion interrupt, software must disable the  $\mu$ DMA transmit enable to the SSI by clearing the `TXDMAE` bit in the **QSSI DMA Control (SSIDMACTL)** register and then setting the `DMATXIC` bit in the **SSIICR** register. This clears the DMA completion interrupt. When the  $\mu$ DMA is needed to transmit more data, the `TXDMAE` bit must be set (enabled) again.

7. If this is the first initialization out of reset, enable the QSSI by setting the `SSE` bit in the **SSICR1** register.

As an example, assume the QSSI must be configured to operate with the following parameters:

- Master operation
- Freescale SPI mode (`SPO=1`, `SPH=1`)
- 1 Mbps bit rate
- 8 data bits

Assuming the system clock is 20 MHz, the bit rate calculation would be:

$$\begin{aligned} \text{SSInClk} &= \text{SysClk} / (\text{CPSDVSR} * (1 + \text{SCR})) \\ 1 \times 10^6 &= 20 \times 10^6 / (\text{CPSDVSR} * (1 + \text{SCR})) \end{aligned}$$

In this case, if `CPSDVSR=0x2`, `SCR` must be `0x9`.

The configuration sequence would be as follows:

1. Ensure that the `SSE` bit in the **SSICR1** register is clear.
2. Write the **SSICR1** register with a value of `0x0000.0000`.
3. Write the **SSICPSR** register with a value of `0x0000.0002`.
4. Write the **SSICR0** register with a value of `0x0000.09C7`.
5. The QSSI is then enabled by setting the `SSE` bit in the **SSICR1** register.

## 20.4.1 Enhanced Mode Configuration

If the QSSI module supports the Advanced/Bi-/Quad features, then these modes can be enabled after initializing the QSSI module. Below is an example of configuring the QSSI to transmit two data bytes in Advanced SSI mode followed by 2 bytes in Bi-SSI mode:

1. Set the `MODE` bit to `0x3`, and the `FSSHLDLFM` bit to 1 in the **SSICR1** register. To operate in the master mode, program the `MS` bit to 0. Program the remaining bits in the **SSICR0** and **SSICR1** register to relevant values.
2. Write one data byte to the TX FIFO; set the `EOM` bit to 1 and write the second data byte to the TX FIFO.

3. Set the `MODE` bit to 0x1 and the `FSSHLD` bit to 1 in the **SSICR1** register. To operate in the master mode, program the `MS` bit to 0. Program the remaining bits in the **SSICR0** and **SSICR1** register to relevant values.
4. Fill the Tx FIFO with one data byte.
5. Set the `EOM` bit in the **SSICR1** register.
6. Fill the Tx FIFO with one data byte.

## 20.5 Register Map

Table 20-5 on page 1354 lists the QSSI registers. The offset listed is a hexadecimal increment to the register's address, relative to that QSSI module's base address:

- QSSI0: 0x4000.8000
- QSSI1: 0x4000.9000
- QSSI2: 0x4000.A000
- QSSI3: 0x4000.B000

Note that the QSSI module clock must be enabled before the registers can be programmed (see page 388). The `Rn` bit of the **PRSSI** register must be read as 0x1 before any QSSI module registers are accessed.

**Table 20-5. SSI Register Map**

| Offset | Name         | Type | Reset       | Description                      | See page |
|--------|--------------|------|-------------|----------------------------------|----------|
| 0x000  | SSICR0       | RW   | 0x0000.0000 | QSSI Control 0                   | 1356     |

## 20.6 Register Descriptions

The remainder of this section lists and describes the QSSI registers, in numerical order by address offset.

### Register 1: QSSI Control 0 (SSICR0), offset 0x000

The **SSICR0** register contains bit fields that control various functions within the QSSI module. Functionality such as protocol mode, clock rate, and data size are configured in this register.

#### QSSI Control 0 (SSICR0)

QSSI0 base: 0x4000.8000  
 QSSI1 base: 0x4000.9000  
 QSSI2 base: 0x4000.A000  
 QSSI3 base: 0x4000.B000  
 Offset 0x000  
 Type RW, reset 0x0000.0000

| Bit/Field | Name   | Type | Reset  | Description  |       |             |   |  |   |  |
|-----------|--|------|--------|--|-------|-------------|---|--|---|--|
| 31:16     | reserved   | RO   | 0x0000 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.  |       |             |   |  |   |  |
| 15:8      | SCR  | RW   | 0x00   | <p>QSSI Serial Clock Rate</p> <p>This bit field is used to generate the transmit and receive bit rate of the QSSI. The bit rate is:</p> $BR = SysClk / (CPSDVSR * (1 + SCR))$ <p>where CPSDVSR is an even value from 2-254 programmed in the <b>SSICPSR</b> register, and SCR is a value from 0-255.</p>   |       |             |   |  |   |  |
| 7         | SPH  | RW   | 0      | <p>QSSI Serial Clock Phase</p> <p>This bit is only applicable to the Freescale SPI Format.</p> <p>The SPH control bit selects the clock edge that captures data and allows it to change state. This bit has the most impact on the first bit transmitted by either allowing or not allowing a clock transition before the first data capture edge.</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>Data is captured on the first clock edge transition.</td> </tr> <tr> <td>1</td> <td>Data is captured on the second clock edge transition.</td> </tr> </tbody> </table> | Value | Description | 0 | Data is captured on the first clock edge transition.   | 1 | Data is captured on the second clock edge transition.                                      |
| Value     | Description  |      |        |  |       |             |   |  |   |  |
| 0         | Data is captured on the first clock edge transition.                                       |      |        |  |       |             |   |  |   |  |
| 1         | Data is captured on the second clock edge transition.                                      |      |        |  |       |             |   |  |   |  |
| 6         | SPO  | RW   | 0      | <p>QSSI Serial Clock Polarity</p> <table border="1"> <thead> <tr> <th>Value</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>A steady state Low value is placed on the SSInClk pin.</td> </tr> <tr> <td>1</td> <td>A steady state High value is placed on the SSInClk pin when data is not being transferred.</td> </tr> </tbody> </table> <p><b>Note:</b> If this bit is set, then software must also configure the GPIO port pin corresponding to the SSInClk signal as a pull-up in the <b>GPIO Pull-Up Select (GPIOPUR)</b> register.</p>  | Value | Description | 0 | A steady state Low value is placed on the SSInClk pin. | 1 | A steady state High value is placed on the SSInClk pin when data is not being transferred. |
| Value     | Description  |      |        |  |       |             |   |  |   |  |
| 0         | A steady state Low value is placed on the SSInClk pin.                                     |      |        |  |       |             |   |  |   |  |
| 1         | A steady state High value is placed on the SSInClk pin when data is not being transferred. |      |        |  |       |             |   |  |   |  |

| Bit/Field | Name | Type | Reset | Description  |
|-----------|------|------|-------|--|
| 5:4       | FRF  | RW   | 0x0   | <p>QSSI Frame Format Select</p> <p><b>Note:</b> When operating in Advanced/Bi-/Quad-SSI mode these bits must be programmed to 0x0 (Freescale SPI Frame Format).</p> <p>Value    Frame Format</p> <p>0x0      Freescale SPI Frame Format</p> <p>0x1      Texas Instruments Synchronous Serial Frame Format</p> <p>0x2-0x3 Reserved</p>  |
| 3:0       | DSS  | RW   | 0x0   | <p>QSSI Data Size Select</p> <p><b>Note:</b> When operating in Advanced, Bi- or Quad-SSI, data size can only be 8-bit. All other fields will be ignored.</p> <p>Value    Data Size</p> <p>0x0-0x2 Reserved</p> <p>0x3      4-bit data</p> <p>0x4      5-bit data</p> <p>0x5      6-bit data</p> <p>0x6      7-bit data</p> <p>0x7      8-bit data</p> <p>0x8      9-bit data</p> <p>0x9      10-bit data</p> <p>0xA      11-bit data</p> <p>0xB      12-bit data</p> <p>0xC      13-bit data</p> <p>0xD      14-bit data</p> <p>0xE      15-bit data</p> <p>0xF      16-bit data</p> |

## Register 2: QSSI Control 1 (SSICR1), offset 0x004

The **SSICR1** register contains bit fields that control various functions within the QSSI module. Master and slave mode functionality is controlled by this register.

### QSSI Control 1 (SSICR1)

### Register 3: QSSI Data (SSIDR), offset 0x008

**Important:** This register is read-sensitive. See the register description for details.

The **SSIDR** register is 16-bits wide. When the **SSIDR** register is read, the entry in the receive FIFO that is pointed to by the current FIFO read pointer is accessed. When a data value is removed by the QSSI receive logic from the incoming data frame, it is placed into the entry in the receive FIFO pointed to by the current FIFO write pointer.

When the **SSIDR** register is written to, the entry in the transmit FIFO that is pointed to by the write pointer is written to. Data values are removed from the transmit FIFO one value at a time by the transmit logic. Each data value is loaded into the transmit serial shifter, then serially shifted out onto the **SSInDAT0/SSInTX** pin at the programmed bit rate.

When a data size of less than 16 bits is selected, the user must right-justify data written to the transmit FIFO. The transmit logic ignores the unused bits. Received data less than 16 bits is automatically right-justified in the receive buffer.

#### QSSI Data (SSIDR)

QSSI0 base: 0x4000.8000  
 QSSI1 base: 0x4000.9000  
 QSSI2 base: 0x4000.A000  
 QSSI3 base: 0x4000.B000  
 Offset 0x008  
 Type RW, reset 0x0000.0000

| Bit/Field | Name     | Type | Reset  | Description   |
|-----------|----------|------|--------|---|
| 31:16     | reserved | RO   | 0x0000 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.   |
| 15:0      | DATA     | RW   | 0x0000 | QSSI Receive/Transmit Data<br>A read operation reads the receive FIFO. A write operation writes the transmit FIFO.<br>Software must right-justify data when the QSSI is programmed for a data size that is less than 16 bits. Unused bits at the top are ignored by the transmit logic. The receive logic automatically right-justifies the data. |

**Register 4: QSSI Status (SSISR), offset 0x00C**

The **SSISR** register contains bits that indicate the FIFO fill status and the QSSI busy status.

**QSSI Status (SSISR)**

QSSI0 base: 0x4000.8000

QSSI1 base: 0x4000.9000

QSSI2 base: 0x4000.A000

QSSI3 base: 0x4000.B000

Offset 0x00C

**Register 5: QSSI Clock Prescale (SSICPSR), offset 0x010**

The **SSICPSR** register specifies the division factor which is used to derive the **SSInClk** from the system clock. The clock is further divided by a value from 1 to 256, which is  $1 + \text{SCR}$ . **SCR** is programmed in the **SSICR0** register. The frequency of the **SSInClk** is defined by:

$$\text{SSInClk} = \text{SysClk} / (\text{CPSDVSR} * (1 + \text{SCR}))$$

The value programmed into this register must be an even number between 2 and 254. The least-significant bit of the programmed number is hard-coded to zero. If an odd number is written to this register, data read back from this register has the least-significant bit as zero.

### Register 6: QSSI Interrupt Mask (SSIIM), offset 0x014

The **SSIIM** register is the interrupt mask set or clear register. It is a read/write register and all bits are cleared on reset.

On a read, this register gives the current value of the mask on the corresponding interrupt. Setting a bit clears the mask, enabling the interrupt to be sent to the interrupt controller. Clearing a bit sets the corresponding mask, preventing the interrupt from being signaled to the controller.

#### QSSI Interrupt Mask (SSIIM)

**Register 12: QSSI Clock Configuration (SSICC), offset 0xFC8**

The **SSICC** register controls the baud clock source for the QSSI module.

**Note:** If ALTCLK is used for the QSSI baud clock, the system clock frequency must be at least twice that of the ALTCLK programmed value in Run mode.

**QSSI Clock Configuration (SSICC)**

## 21 Inter-Integrated Circuit (I<sup>2</sup>C) Interface

The Inter-Integrated Circuit (I<sup>2</sup>C) bus provides bi-directional data transfer through a two-wire design (a serial data line SDA and a serial clock line SCL), and interfaces to external I<sup>2</sup>C devices such as serial memory (RAMs and ROMs), networking devices, LCDs, tone generators, and so on. The I<sup>2</sup>C bus may also be used for system testing and diagnostic purposes in product development and manufacturing. The TM4C129CNCZAD microcontroller includes providing the ability to communicate (both transmit and receive) with other I<sup>2</sup>C devices on the bus.

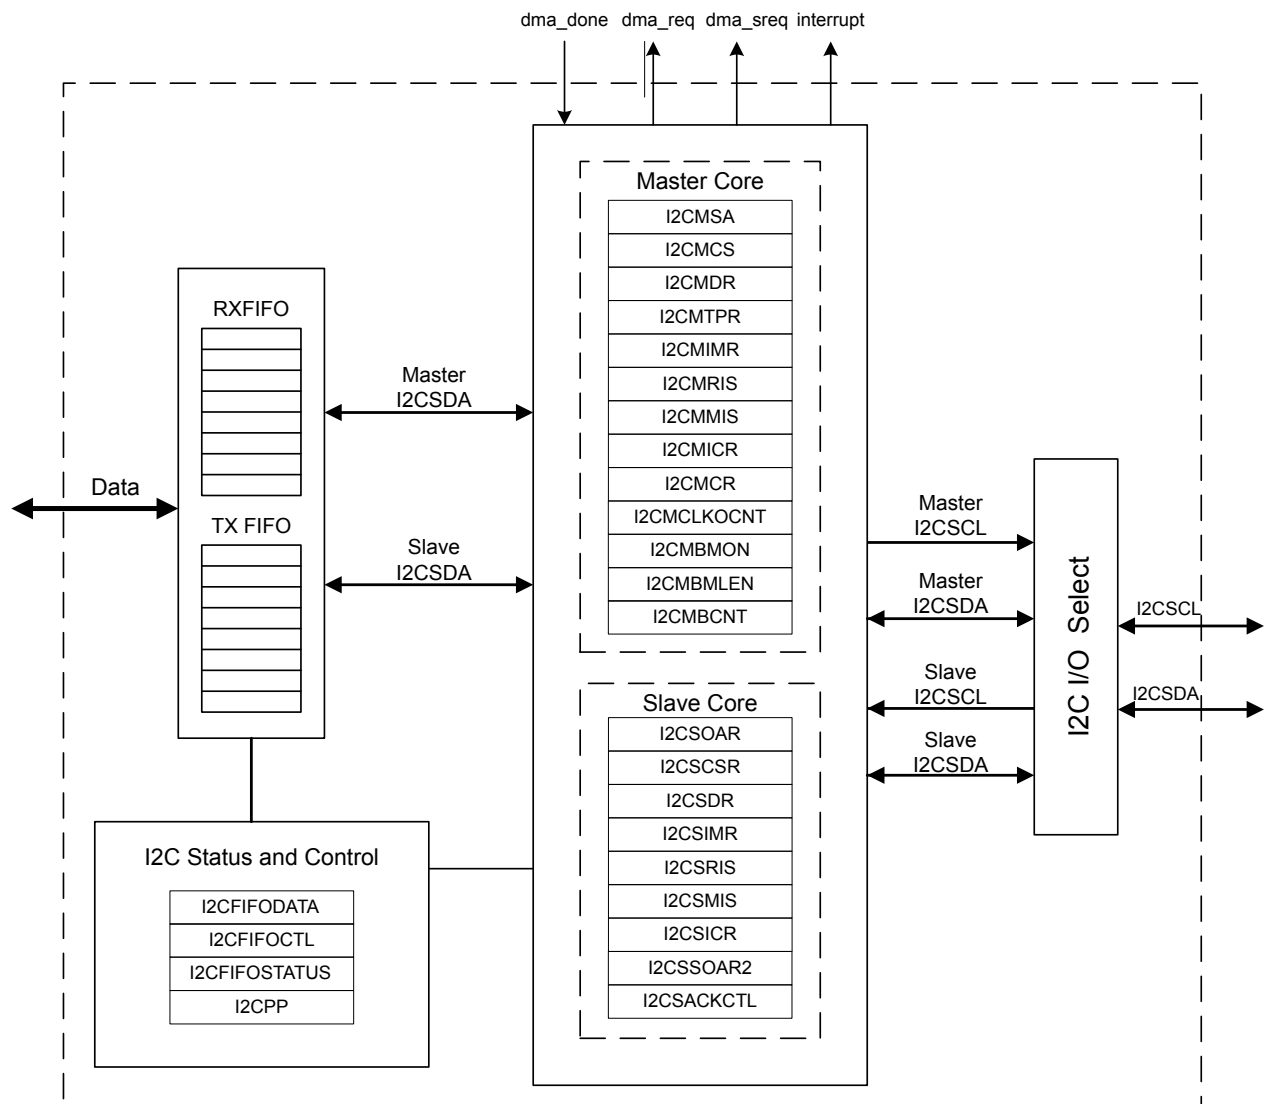

The TM4C129CNCZAD controller includes I<sup>2</sup>C modules with the following features:

- Devices on the I<sup>2</sup>C bus can be designated as either a master or a slave
  - Supports both transmitting and receiving data as either a master or a slave
  - Supports simultaneous master and slave operation
- Four I<sup>2</sup>C modes
  - Master transmit
  - Master receive
  - Slave transmit
  - Slave receive
- Two 8-entry FIFOs for receive and transmit data
  - FIFOs can be independently assigned to master or slave
- Four transmission speeds:
  - Standard (100 Kbps)
  - Fast-mode (400 Kbps)
  - Fast-mode plus (1 Mbps)
  - High-speed mode (3.33 Mbps)
- Glitch suppression
- SMBus support through software
  - Clock low timeout interrupt
  - Dual slave address capability
  - Quick command capability
- Master and slave interrupt generation
  - Master generates interrupts when a transmit or receive operation completes (or aborts due to an error)

- Slave generates interrupts when data has been transferred or requested by a master or when a START or STOP condition is detected
- Master with arbitration and clock synchronization, multimaster support, and 7-bit addressing mode
- Efficient transfers using Micro Direct Memory Access Controller (μDMA)
- Separate channels for transmit and receive
- Ability to execute single data transfers or burst data transfers using the RX and TX FIFOs in the I<sup>2</sup>C

## 21.1 Block Diagram

Figure 21-1. I<sup>2</sup>C Block Diagram

## 21.2 Signal Description

The following table lists the external signals of the I<sup>2</sup>C interface and describes the function of each. The I<sup>2</sup>C interface signals are alternate functions for some GPIO signals and default to be GPIO signals at reset. The column in the table below titled "Pin Mux/Pin Assignment" lists the possible GPIO pin placements for the I<sup>2</sup>C signals. The **AFSEL** bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 762) should be set to choose the I<sup>2</sup>C function. The number in parentheses is the encoding that must be programmed into the **PMC<sub>n</sub>** field in the **GPIO Port Control (GPIOPTL)** register (page 779) to assign the I<sup>2</sup>C signal to the specified GPIO port pin. Note that the **I2CSDA** pin should be set to open drain using the **GPIO Open Drain Select (GPIOODR)** register. For more information on configuring GPIOs, see "General-Purpose Input/Outputs (GPIOs)" on page 731.

**Table 21-1. I2C Signals (212BGA)**

| Pin Name | Pin Number                    | Pin Mux / Pin Assignment                            | Pin Type | Buffer Type | Description  |

## 21.3 Functional Description

Each I<sup>2</sup>C module is comprised of both master and slave functions and is identified by a unique address. A master-initiated communication generates the clock signal, SCL. For proper operation, the SDA pin must be configured as an open-drain signal. Due to the internal circuitry that supports high-speed operation, the SCL pin must not be configured as an open-drain signal, although the internal circuitry causes it to act as if it were an open drain signal. Both SDA and SCL signals must be connected to a positive supply voltage using a pull-up resistor. A typical I<sup>2</sup>C bus configuration is shown in Figure 21-2. Refer to the *I<sup>2</sup>C-bus specification and user manual* to determine the size of the pull-ups needed for proper operation.

See “Inter-Integrated Circuit (I<sup>2</sup>C) Interface” on page 1757 for I<sup>2</sup>C timing diagrams.

Figure 21-2. I<sup>2</sup>C Bus Configuration

### 21.3.1 I<sup>2</sup>C Bus Functional Overview

The I<sup>2</sup>C bus uses only two signals: SDA and SCL, named I2CSDA and I2CSCL on TM4C129CNCZAD microcontrollers. SDA is the bi-directional serial data line and SCL is the bi-directional serial clock line. The bus is considered idle when both lines are High.

Every transaction on the I<sup>2</sup>C bus is nine bits long, consisting of eight data bits and a single acknowledge bit. The number of bytes per transfer (defined as the time between a valid START and STOP condition, described in “START and STOP Conditions” on page 1390) is unrestricted, but each data byte has to be followed by an acknowledge bit, and data must be transferred MSB first. When a receiver cannot receive another complete byte, it can hold the clock line SCL Low and force the transmitter into a wait state. The data transfer continues when the receiver releases the clock SCL.

### 21.3.1.1 START and STOP Conditions

The protocol of the I<sup>2</sup>C bus defines two states to begin and end a transaction: START and STOP. A High-to-Low transition on the SDA line while the SCL is High is defined as a START condition, and a Low-to-High transition on the SDA line while SCL is High is defined as a STOP condition. The bus is considered busy after a START condition and free after a STOP condition. See Figure 21-3.

**Figure 21-3. START and STOP Conditions**

The STOP bit determines if the cycle stops at the end of the data cycle or continues on to a repeated START condition. To generate a single transmit cycle, the **I<sup>2</sup>C Master Slave Address (I2CMSA)** register is written with the desired address, the R/S bit is cleared, and the Control register is written with ACK=X (0 or 1), STOP=1, START=1, and RUN=1 to perform the operation and stop. When the operation is completed (or aborted due to an error), the interrupt pin becomes active and the data may be read from the **I<sup>2</sup>C Master Data (I2CMDR)** register. When the I<sup>2</sup>C module operates in Master receiver mode, the ACK bit is normally set causing the I<sup>2</sup>C bus controller to transmit an acknowledge automatically after each byte. This bit must be cleared when the I<sup>2</sup>C bus controller requires no further data to be transmitted from the slave transmitter.

When operating in slave mode, the STARTRIS and STOPRIS bits in the **I<sup>2</sup>C Slave Raw Interrupt Status (I2CSRIS)** register indicate detection of start and stop conditions on the bus and the **I<sup>2</sup>C Slave Masked Interrupt Status (I2CSMIS)** register can be configured to allow STARTRIS and STOPRIS to be promoted to controller interrupts (when interrupts are enabled).

### 21.3.1.2 Data Format with 7-Bit Address

Data transfers follow the format shown in Figure 21-4. After the START condition, a slave address is transmitted. This address is 7-bits long followed by an eighth bit, which is a data direction bit (R/S bit in the **I2CMSA** register). If the R/S bit is clear, it indicates a transmit operation (send), and if it is set, it indicates a request for data (receive). A data transfer is always terminated by a STOP condition generated by the master, however, a master can initiate communications with another device on the bus by generating a repeated START condition and addressing another slave without first generating a STOP condition. Various combinations of receive/transmit formats are then possible within a single transfer.

**Figure 21-4. Complete Data Transfer with a 7-Bit Address**

The first seven bits of the first byte make up the slave address (see Figure 21-5). The eighth bit determines the direction of the message. A zero in the R/S position of the first byte means that the master transmits (sends) data to the selected slave, and a one in this position means that the master receives data from the slave.

**Figure 21-5. R/S Bit in First Byte**

### 21.3.1.3 Data Validity

The data on the SDA line must be stable during the high period of the clock, and the data line can only change when SCL is Low (see Figure 21-6).

**Figure 21-6. Data Validity During Bit Transfer on the I<sup>2</sup>C Bus**

### 21.3.1.4 Acknowledge

All bus transactions have a required acknowledge clock cycle that is generated by the master. During the acknowledge cycle, the transmitter (which can be the master or slave) releases the SDA line. To acknowledge the transaction, the receiver must pull down SDA during the acknowledge clock cycle. The data transmitted out by the receiver during the acknowledge cycle must comply with the data validity requirements described in “Data Validity” on page 1391.

When a slave receiver does not acknowledge the slave address, SDA must be left High by the slave so that the master can generate a STOP condition and abort the current transfer. If the master device is acting as a receiver during a transfer, it is responsible for acknowledging each transfer made by the slave. Because the master controls the number of bytes in the transfer, it signals the end of data to the slave transmitter by not generating an acknowledge on the last data byte. The slave transmitter must then release SDA to allow the master to generate the STOP or a repeated START condition.

If the slave is required to provide a manual ACK or NACK, the **I<sup>2</sup>C Slave ACK Control (I2CSACKCTL)** register allows the slave to NACK for invalid data or command or ACK for valid data or command. When this operation is enabled, the MCU slave module I<sup>2</sup>C clock is pulled low after the last data bit until this register is written with the indicated response.

### 21.3.1.5 Repeated Start

The I<sup>2</sup>C master module has the capability of executing a repeated START (transmit or receive) after an initial transfer has occurred.

A repeated start sequence for a Master transmit is as follows:

1. When the device is in the idle state, the Master writes the slave address to the **I2CMSA** register and configures the R/S bit for the desired transfer type.
2. Data is written to the **I2CMDR** register.
3. When the **BUSY** bit in the **I2CMCS** register is 0, the Master writes 0x3 to the **I2CMCS** register to initiate a transfer.
4. The Master does not generate a STOP condition but instead writes another slave address to the **I2CMSA** register and then writes 0x3 to initiate the repeated START.

A repeated start sequence for a Master receive is similar:

1. When the device is in idle, the Master writes the slave address to the **I2CMSA** register and configures the R/S bit for the desired transfer type.
2. The master reads data from the **I2CMDR** register.
3. When the **BUSY** bit in the **I2CMCS** register is 0, the Master writes 0x3 to the **I2CMCS** register to initiate a transfer.
4. The Master does not generate a STOP condition but instead writes another slave address to the **I2CMSA** register and then writes 0x3 to initiate the repeated START.

For more information on repeated START, refer to Figure 21-12 on page 1405 and Figure 21-13 on page 1406.

### 21.3.1.6 Clock Low Timeout (CLTO)

The I<sup>2</sup>C slave can extend the transaction by pulling the clock low periodically to create a slow bit transfer rate. The I<sup>2</sup>C module has a 12-bit programmable counter that is used to track how long the clock has been held low. The upper 8 bits of the count value are software programmable through the **I<sup>2</sup>C Master Clock Low Timeout Count (I2CMCLKOCNT)** register. The lower four bits are not user visible and are 0x0. The **CNTL** value programmed in the **I2CMCLKOCNT** register has to be greater than 0x01. The application can program the eight most significant bits of the counter to reflect the acceptable cumulative low period in transaction. The count is loaded at the START condition and counts down on each falling edge of the internal bus clock of the Master. Note that the internal bus clock generated for this counter keeps running at the programmed I<sup>2</sup>C speed even if SCL is held low on the bus. Upon reaching terminal count, the master state machine forces ABORT on the bus by issuing a STOP condition at the instance of SCL and SDA release.

As an example, if an I<sup>2</sup>C module was operating at 100 kHz speed, programming the **I2CMCLKOCNT** register to 0xDA would translate to the value 0xDA0 since the lower four bits are set to 0x0. This would translate to a decimal value of 3488 clocks or a cumulative clock low period of 34.88 ms at 100 kHz.

The **CLKRIS** bit in the **I<sup>2</sup>C Master Raw Interrupt Status (I2CMRIS)** register is set when the clock timeout period is reached, allowing the master to start corrective action to resolve the remote slave state. In addition, the **CLKTO** bit in the **I<sup>2</sup>C Master Control/Status (I2CMCS)** register is set; this bit

is cleared when a STOP condition is sent or during the I<sup>2</sup>C master reset. The status of the raw SDA and SCL signals are readable by software through the *SDA* and *SCL* bits in the **I<sup>2</sup>C Master Bus Monitor (I2CMBMON)** register to help determine the state of the remote slave.

In the event of a CLTO condition, application software must choose how it intends to attempt bus recovery. Most applications may attempt to manually toggle the I<sup>2</sup>C pins to force the slave to let go of the clock signal (a common solution is to attempt to force a STOP on the bus). If a CLTO is detected before the end of a burst transfer, and the bus is successfully recovered by the master, the master hardware attempts to finish the pending burst operation. Depending on the state of the slave after bus recovery, the actual behavior on the bus varies. If the slave resumes in a state where it can acknowledge the master (essentially, where it was before the bus hang), it continues where it left off. However, if the slave resumes in a reset state (or if a forced STOP by the master causes the slave to enter the idle state), it may ignore the master's attempt to complete the burst operation and NAK the first data byte that the master sends or requests.

Since the behavior of slaves cannot always be predicted, it is suggested that the application software always write the *STOP* bit in the **I<sup>2</sup>C Master Configuration (I2CMCR)** register during the CLTO interrupt service routine. This limits the amount of data the master attempts to send or receive upon bus recovery to a single byte, and after the single byte is on the wire, the master issues a STOP. An alternative solution is to have the application software reset the I<sup>2</sup>C peripheral before attempting to manually recover the bus. This solution allows the I<sup>2</sup>C master hardware to be returned to a known good (and idle) state before attempting to recover a stuck bus and prevents any unwanted data from appearing on the wire.

**Note:** The Master Clock Low Timeout counter counts for the entire time *SCL* is held Low continuously. If *SCL* is deasserted at any point, the Master Clock Low Timeout Counter is reloaded with the value in the **I2CMCLKOCNT** register and begins counting down from this value.

### 21.3.1.7 Dual Address

The I<sup>2</sup>C interface supports dual address capability for the slave. The additional programmable address is provided and can be matched if enabled. In legacy mode with dual address disabled, the I<sup>2</sup>C slave provides an ACK on the bus if the address matches the *OAR* field in the **I2CSOAR** register. In dual address mode, the I<sup>2</sup>C slave provides an ACK on the bus if either the *OAR* field in the **I2CSOAR** register or the *OAR2* field in the **I2CSOAR2** register is matched. The enable for dual address is programmable through the *OAR2EN* bit in the **I2CSOAR2** register and there is no disable on the legacy address.

The *OAR2SEL* bit in the **I2CSCSR** register indicates if the address that was ACKed is the alternate address or not. When this bit is clear, it indicates either legacy operation or no address match.

### 21.3.1.8 Arbitration

A master may start a transfer only if the bus is idle. It's possible for two or more masters to generate a START condition within minimum hold time of the START condition. In these situations, an arbitration scheme takes place on the SDA line, while SCL is High. During arbitration, the first of the competing master devices to place a 1 (High) on SDA, while another master transmits a 0 (Low), switches off its data output stage and retires until the bus is idle again.

Arbitration can take place over several bits. Its first stage is a comparison of address bits, and if both masters are trying to address the same device, arbitration continues on to the comparison of data bits.

If arbitration is lost when the I2C master is initiating a BURST with the TX FIFO enabled, the application should execute the following steps to correctly handle the arbitration loss:

1. Flush and disable the TX FIFO
2. Clear and mask the TXFE interrupt by clearing the TXFEIM bit in the **I2CMIMR** register.

Once the bus is IDLE, the TXFIFO can be filled and enabled, the TXFE bit can be unmasked and a new BURST transaction can be initiated.

### 21.3.1.9 Glitch Suppression in Multi-Master Configuration

When a multi-master configuration is being used, the PULSEL bit in the **I2CMTPR** register can be programmed to provide glitch suppression on the SCL and SDA lines and assure proper signal values. The glitch suppression value is in terms of buffered system clocks. Note that all signals will be delayed internally when glitch suppression is nonzero. For example, if PULSEL is set to 0x7, 31 clocks should be added onto the calculation for the expected transaction time.

### 21.3.1.10 SMBus Operation

The SMBus interface is based on the I<sup>2</sup>C protocol; however, some differences exist between the two. These differences must be handled through software in order to make sure the SMBus protocol, including timing specifications, is met. Note that the SMBus 2.0 specification limits the maximum frequency of the interface to 100 KHz, as a result, I<sup>2</sup>C Standard speed operation is used for SMBus.

The SMBus/ I<sup>2</sup>C slave can extend the transaction if it is not ready by pulling the clock low. The SMBus specification allows the maximum timeout for such elongated transaction to be between 25 to 35 ms. The I<sup>2</sup>C specification does not have this requirement. The I<sup>2</sup>C module supports a programmable count to support clock-low timeout for the master to error out and take appropriate action as required. This feature is explained in "Clock Low Timeout (CLTO)" on page 1392. Note that if transactions are extended, a timeout period should be programmed in the **I2CMCLKOCNT** register, and the CLKRIS bit in the **I2CMRIS** register should not be masked.

Unlike the I<sup>2</sup>C slave, the SMBus slave must respond with an ACK response to its address regardless of whether it is ready or not. As a result, the I<sup>2</sup>C slave sends an ACK response to its address and a NACK response on the data byte if it is not ready. The ARBLST bit in the **I2CMCS** register is set if there were any issues with the transfer. In addition, the slave can send a NACK at any time to force the master to stop sending additional bytes.

The I<sup>2</sup>C Interface supports  $\mu$ DMA for efficient data handling. The  $\mu$ DMA operation needs FIFOs to be enabled for appropriate transfer type to perform I<sup>2</sup>C Master for burst transfers and all types of Slave transfers. The I<sup>2</sup>C interface is supported by two channels, one for Rx (I<sup>2</sup>C to Memory) and one for Tx (Memory to I<sup>2</sup>C) transfers.. See "FIFO and  $\mu$ DMA Operation" on page 1398 for more information.

#### Quick Command

Quick Command is a simple, compact SMBus protocol that sends an address and 1-bit of data in the R/S bit of the I<sup>2</sup>C header byte to communicate a command to the slave, typically a "turn off" or "turn on". The I<sup>2</sup>C master peripheral has the ability to send a Quick Command by writing the target address and R/S value into the **I2CMSA** register followed by a write to **I2CMCS** with a value of 0x27. SMBus requires the slave to be able to accept and process commands and the master to generate the Quick Command transactions. The master also has the capability to stop the transaction after acknowledgement from a slave.

The I<sup>2</sup>C slave peripheral requires special handling when a Quick Command is sent. In the case where a master sends a Quick Command with the R/S (data) bit cleared, the QCMDST bit in **I2CSCSR** is set, and the QCMDRW bit shows the data value (which in this case is 0) when the STOPRIS bit is set in **I2CSRIS** and the STOP interrupt is asserted. In this scenario, a DATARIS interrupt bit is not

set. When the master sends a Quick Command with the R/S (data) bit set, the DATARIS bit is set to notify the slave to write a data byte to **I2CSDR** in which bit 7 is set. A “dummy write” of 0xFF to the **I2CSDR** register is recommended. After the write to **I2CSDR**, the STOP interrupt is asserted and the QCMDST and QCMDRW bits are set in the **I2CSCSR** register to indicate that a quick command read occurred and the last transaction was a Quick Command. Therefore, when the slave must receive a Quick Command, it should be expecting such a command because it must write the **I2CSDR** with a specific value when R/S is set.

### 21.3.2 Available Speed Modes

The I<sup>2</sup>C bus can run in Standard mode (100 kbps), Fast mode (400 kbps), Fast mode plus (1 Mbps) or High-Speed mode (3.4 Mbps, provided correct system clock frequency is set and there is appropriate pull strength on SCL and SDA lines). The selected mode should match the speed of the other I<sup>2</sup>C devices on the bus.

#### 21.3.2.1 Standard, Fast, and Fast Plus Modes

Standard, Fast, and Fast Plus modes are selected using a value in the **I<sup>2</sup>C Master Timer Period (I2CMTPR)** register that results in an SCL frequency of 100 kbps for Standard mode, 400 kbps for Fast mode, or 1 Mbps for Fast mode plus.

The I<sup>2</sup>C clock rate is determined by the parameters *CLK\_PRD*, *TIMER\_PRD*, *SCL\_LP*, and *SCL\_HP* where:

*CLK\_PRD* is the system clock period

*SCL\_LP* is the low phase of SCL (fixed at 6)

*SCL\_HP* is the high phase of SCL (fixed at 4)

*TIMER\_PRD* is the programmed value in the **I2CMTPR** register (see page 1424). This value is determined by replacing the known variables in the equation below and solving for *TIMER\_PRD*.

The I<sup>2</sup>C clock period is calculated as follows:

$$SCL\_PERIOD = 2 \times (1 + TIMER\_PRD) \times (SCL\_LP + SCL\_HP) \times CLK\_PRD$$

For example:

$$CLK\_PRD = 50 \text{ ns}$$

$$TIMER\_PRD = 2$$

$$SCL\_LP = 6$$

$$SCL\_HP = 4$$

yields a SCL frequency of:

$$1/SCL\_PERIOD = 333 \text{ Khz}$$

Table 21-2 gives examples of the timer periods that should be used to generate Standard, Fast mode, and Fast mode plus SCL frequencies based on various system clock frequencies.

**Table 21-2. Examples of I<sup>2</sup>C Master Timer Period Versus Speed Mode**

| System Clock | Timer Period | Standard Mode | Timer Period | Fast Mode | Timer Period | Fast Mode Plus |
|--------------|--------------|---------------|--------------|-----------|--------------|----------------|
| 4 MHz        | 0x01         | 100 Kbps      | -            | -         | -            | -              |
| 6 MHz        | 0x02         | 100 Kbps      | -            | -         | -            | -              |

**Table 21-2. Examples of I<sup>2</sup>C Master Timer Period Versus Speed Mode (continued)**

| System Clock | Timer Period | Standard Mode | Timer Period | Fast Mode | Timer Period | Fast Mode Plus |
|--------------|--------------|---------------|--------------|-----------|--------------|----------------|
| 12.5 MHz     | 0x06         | 89 Kbps       | 0x01         | 312 Kbps  | -            | -              |
| 16.7 MHz     | 0x08         | 93 Kbps       | 0x02         | 278 Kbps  | -            | -              |
| 20 MHz       | 0x09         | 100 Kbps      | 0x02         | 333 Kbps  | -            | -              |
| 25 MHz       | 0x0C         | 96.2 Kbps     | 0x03         | 312 Kbps  | -            | -              |
| 33 MHz       | 0x10         | 97.1 Kbps     | 0x04         | 330 Kbps  | -            | -              |
| 40 MHz       | 0x13         | 100 Kbps      | 0x04         | 400 Kbps  | 0x01         | 1000 Kbps      |
| 50 MHz       | 0x18         | 100 Kbps      | 0x06         | 357 Kbps  | 0x02         | 833 Kbps       |
| 80 MHz       | 0x27         | 100 Kbps      | 0x09         | 400 Kbps  | 0x03         | 1000 Kbps      |
| 100 MHz      | 0x31         | 100 Kbps      | 0x0C         | 385 Kbps  | 0x04         | 1000 Kbps      |
| 120 MHz      | 0x3B         | 100 Kbps      | 0xE          | 400 Kbps  | 0x5          | 1000 Kbps      |

### 21.3.2.2 High-Speed Mode

The TM4C129CNCZAD I<sup>2</sup>C peripheral has support for High-speed operation as both a master and slave. High-Speed mode is configured by setting the HS bit in the **I<sup>2</sup>C Master Control/Status (I2CMCS)** register. High-Speed mode transmits data at a high bit rate with a 66.6%/33.3% duty cycle, but communication and arbitration are done at Standard, Fast mode, or Fast-mode plus speed, depending on which is selected by the user. When the HS bit in the **I2CMCS** register is set, current mode pull-ups are enabled.

The clock period can be selected using the equation below, but in this case, SCL\_LP=2 and SCL\_HP=1.

$$SCL\_PERIOD = 2 \times (1 + TIMER\_PRD) \times (SCL\_LP + SCL\_HP) \times CLK\_PRD$$

So for example:

$$CLK\_PRD = 25 \text{ ns}$$

$$TIMER\_PRD = 1$$

$$SCL\_LP=2$$

$$SCL\_HP=1$$

yields a SCL frequency of:

$$1/T = 3.33 \text{ Mhz}$$

Table 21-3 on page 1396 gives examples of timer period and system clock in High-Speed mode. Note that the HS bit in the **I2CMTPR** register needs to be set for the TPR value to be used in High-Speed mode.

**Table 21-3. Examples of I<sup>2</sup>C Master Timer Period in High-Speed Mode**

| System Clock | Timer Period | Transmission Mode |
|--------------|--------------|-------------------|
| 40 MHz       | 0x01         | 3.33 Mbps         |
| 50 MHz       | 0x02         | 2.77 Mbps         |
| 80 MHz       | 0x03         | 3.33 Mbps         |

When operating as a master, the protocol is shown in Figure 21-7. The master is responsible for sending a master code byte in either Standard (100 Kbps) or Fast-mode (400 Kbps) before it begins

transferring in High-speed mode. The master code byte must contain data in the form of 0000.1XXX and is used to tell the slave devices to prepare for a High-speed transfer. The master code byte should never be acknowledged by a slave since it is only used to indicate that the upcoming data is going to be transferred at a higher data rate. To send the master code byte for a standard high-speed transfer, software should place the value of the master code byte into the **I2CMSA** register and write the **I2CMCS** register with a value of 0x13. If a high-speed burst transfer is required, then to send the master code byte, software should place the value of the master code byte into the **I2CMSA** register and write the **I2CMCS** register with 0x50. Either configuration places the I<sup>2</sup>C master peripheral in High-speed mode, and all subsequent transfers (until STOP) are carried out at High-speed data rate using the normal **I2CMCS** command bits, without setting the HS bit in the **I2CMCS** register. Again, setting the HS bit in the **I2CMCS** register is only necessary during the master code byte.

When operating as a High-speed slave, there is no additional software required.

**Figure 21-7. High-Speed Data Format**

**Note:** High-Speed mode is 3.4 Mbps, provided correct system clock frequency is set and there is appropriate pull strength on SCL and SDA lines.

### 21.3.3 Interrupts

The I<sup>2</sup>C can generate interrupts when the following conditions are observed in the Master Module:

- Master transaction completed (RIS bit)
- Master arbitration lost (ARBLOSTRIS bit)
- Master Address/Data NACK (NACKRIS bit)
- Master bus timeout (CLKRIS bit)
- Next byte request (RIS bit)
- Stop condition on bus detected (STOPRIS bit)
- Start condition on bus detected (STARTRIS bit)
- RX DMA interrupt pending (DMARXRIS bit)
- TX DMA interrupt pending (DMATXRIS bit)
- Trigger value for FIFO has been reached and a TX FIFO request interrupt is pending (TXRIS bit)
- Trigger value for FIFO has been reached and a RX FIFO request interrupt is pending (RXRIS bit)

- Transmit FIFO is empty (TXFERIS bit)
- Receive FIFO is full (RXFFRIS bit)

Interrupts are generated when the following conditions are observed in the Slave Module:

- Slave transaction received (DATARIS bit)
- Slave transaction requested (DATARIS bit)
- Slave next byte transfer request (DATARIS bit)
- Stop condition on bus detected (STOPRIS bit)
- Start condition on bus detected (STARTRIS bit)
- RX DMA interrupt pending (DMARXRIS bit)
- TX DMA interrupt pending (DMATXRIS bit)
- Programmable trigger value for FIFO has been reached and a TX FIFO request interrupt is pending (TXRIS bit)
- Programmable trigger value for FIFO has been reached and a RX FIFO request interrupt is pending (RXRIS bit)
- Transmit FIFO is empty (TXFERIS bit)
- Receive FIFO is full (RXFFRIS bit)

The I<sup>2</sup>C master and I<sup>2</sup>C slave modules have separate interrupt registers. Interrupts can be masked by clearing the appropriate bit in the **I2CMIMR** or **I2CSIMR** register. Note that the RIS bit in the **Master Raw Interrupt Status (I2CMRIS)** register and the DATARIS bit in the **Slave Raw Interrupt Status (I2CSRIS)** register have multiple interrupt causes including a next byte transfer request interrupt. This interrupt is generated when both master and slave are requesting a receive or transmit transaction.

#### **21.3.4 Loopback Operation**

The I<sup>2</sup>C modules can be placed into an internal loopback mode for diagnostic or debug work by setting the LPBK bit in the **I<sup>2</sup>C Master Configuration (I2CMCR)** register. In loopback mode, the SDA and SCL signals from the master and are tied to the SDA and SCL signals of the slave module to allow internal testing of the device without having to go through I/O.

#### **21.3.5 FIFO and $\mu$ DMA Operation**

Both the master and the slave module have the capability to access two 8-byte FIFOs that can be used in conjunction with the  $\mu$ DMA for fast transfer of data. The transmit (TX) FIFO and receive (RX) FIFO can be independently assigned to either the I<sup>2</sup>C master or I<sup>2</sup>C slave. Thus, the following FIFO assignments are allowed:

- The transmit and receive FIFOs can be assigned to the master
- The transmit and receive FIFOs can be assigned to the slave

- The transmit FIFO can be assigned to the master, while the receive FIFO is assigned to the slave and vice versa.

In most cases, both FIFOs will be assigned to either the master or the slave. The FIFO assignment is configured by programming the `TXASGNMT` and `RXASGNMT` bit in the **I<sup>2</sup>C FIFO Control (I2CFIFOCTL)** register.

Each FIFO has a programmable threshold point which indicates when the FIFO service interrupt should be generated. Additionally, a FIFO receive full and transmit empty interrupt can be enabled in the Interrupt Mask (**I2CxIMR**) registers of both the master and slave. Note that if we clear the `TXFERIS` interrupt (by setting the `TXFEIC` bit) when the TX FIFO is empty, the `TXFERIS` interrupt does not reassert even though the TX FIFO remains empty in this situation.

When a FIFO is not assigned to a master or a slave module, the FIFO interrupt and status signals to the module are forced to a state that indicates the FIFO is empty. For example, if the TX FIFO is assigned to the master module, the status signals to the slave transmit interface indicates that the FIFO is empty.

**Note:** The FIFOs must be empty when reassigning the FIFOs for proper functionality

### 21.3.5.1 Master Module Burst Mode

A BURST command is provided for the master module which allows a sequence of data transfers using the  $\mu$ DMA (or software, if desired) to handle the data in the FIFO. The BURST command is enabled by setting the BURST bit in the **Master Control/Status (I2CMCS)** register. The number of bytes transferred by a BURST request is programmed in the **I2C Master Burst Length (I2CMBLEN)** register and a copy of this value is automatically written to the **I2C Master Burst Count (I2CMBCNT)** register to be used as a down-counter during the BURST transfer. The bytes written to the **I2C FIFO Data (I2CFIFODATA)** register are transferred to the RX FIFO or TX FIFO depending on whether a transmit or receive is being executed. If data is NACKed during a BURST and the `STOP` bit is set in the **I2CMCS** register, the transfer terminates. If the `STOP` bit is not set, the software application must issue a repeated `STOP` or `START` when a NACK interrupt is asserted. In the case of a NACK, the **I2CMBCNT** register can be used to determine the amount of data that was transferred prior to the BURST termination. If the Address is NACKed during a transfer, then a `STOP` is issued.

#### **Master Module $\mu$ DMA Functionality**

When the **Master Control/Status (I2CMCS)** register is set to enable BURST and the master I<sup>2</sup>C  $\mu$ DMA channel is enabled in the **DMA Channel Map Select n (DMACHMAPn)** registers in the  $\mu$ DMA, the master control module will assert either the internal single  $\mu$ DMA request signal (`dma_sreq`) or multiple  $\mu$ DMA request signal (`dma_req`) to the  $\mu$ DMA. Note that there are separate `dma_req` and `dma_sreq` signals for transmit and receive. A single  $\mu$ DMA request (`dma_sreq`) will be asserted by the Master module when the Rx FIFO has at least one data byte present in the FIFO and/or when the Tx FIFO has at least one space available to fill. The `dma_req` (or Burst) signal will be asserted when Rx FIFO fill level is higher than trigger level and/or the Tx FIFO burst length remaining is less than 4 bytes and the FIFO fill level is less than trigger level. If a single transfer or BURST operation has completed, the  $\mu$ DMA sends a `dma_done` signal to the master module represented by the `DMATX/DMARX` interrupts in the **I2CMIMR/I2CMRIS/I2CMMIS/I2CMICR** registers.

If the  $\mu$ DMA I<sup>2</sup>C channel is disabled and software is used to handle the BURST command, software can read the **FIFO Status (I2CFIFOSTAT)** Register and the **Master Burst Count (I2CMBC)** register to determine whether the FIFO needs servicing during the BURST transaction. A trigger value can be programmed in the **I2CFIFOCTL** register to allow for interrupts at various fill levels of the FIFOs.

The `NACK` and `ARBLOST` bits in the interrupt status registers can be enabled to indicate no acknowledgement of data transfer or an arbitration loss on the bus.

When the Master module is transmitting FIFO data, software can fill the Tx FIFO in advance of setting the BURST bit in the **I2CMCS** register. If the FIFO is empty when the  $\mu$ DMA is enabled for BURST mode, the `dma_req` and `dma_sreq` both assert (assuming the **I2CMLEN** register is programmed to at least 4 bytes and the Tx FIFO fill level is less than the trigger set). If the **I2CMLEN** register value is less than 4 and the Tx FIFO is not full but more than trigger level, only `dma_sreq` will assert. Single requests will be generated as required to keep the FIFO full until the number of bytes specified in the **I2CMLEN** register has been transferred to the FIFO (and the **I2CMBCOUNT** register reaches 0x0). At this point, no further requests are generated until the next BURST command is issued. If the  $\mu$ DMA is disabled, FIFOs will be serviced based on the interrupts active in the Master interrupt status registers, the FIFO trigger values shown in the **I2CFIFOSTATUS** register and completion of a BURST transfer.

When the Master module is receiving FIFO data, the Rx FIFO is initially empty and no requests are asserted. If data is read from the slave and placed into the Rx FIFO, the `dma_sreq` signal to the  $\mu$ DMA is asserted to indicate there is data to be transferred. If the Rx FIFO contains at least 4 bytes, the `dma_req` signal is also asserted. The  $\mu$ DMA will continue to transfer data out of the Rx FIFO until it has reached the amount of bytes programmed in the **I2CMLEN** register.

**Note:** The `TXFEIM` interrupt mask bit in the **I2CMIMR** register should be clear (masking the `TXFE` interrupt) when the master is performing an RX Burst from the RXFIFO and should be unmasked before starting a TX FIFO transfers.

### 21.3.5.2 Slave Module

The slave module also has the capability to use the  $\mu$ DMA in Rx and Tx FIFO data transfers. If the Tx FIFO is assigned to the slave module and the `TXFIFO` bit is set in the **I2CCSR** register, the slave module will generate a single  $\mu$ DMA request, `dma_sreq`, if the master module requests the next byte transfer. If the FIFO fill level is less than the trigger level, a  $\mu$ DMA multiple transfer request, `dma_req`, will be asserted to continue data transfers from the  $\mu$ DMA.

If the Rx FIFO is assigned to the slave module and the `RXFIFO` bit is set in the **I2CCSR** register, then the slave module will generate a signal  $\mu$ DMA request, `dma_sreq`, if there is any data to be transferred. The `dma_req` signal will be asserted when the Rx FIFO has more data than the trigger level programmed by the `RXTRIG` bit in the **I2CFIFOCTL** register.

**Note:** Best practice recommends that an application should not switch between the **I2CSDR** register and TX FIFO or vice versa for successive transactions.

## 21.3.6 Command Sequence Flow Charts

This section details the steps required to perform the various I<sup>2</sup>C transfer types in both master and slave mode. Refer to Table 21-5 on page 1419 for further sequence information.

### 21.3.6.1 I<sup>2</sup>C Master Command Sequences

The figures that follow show the command sequences available for the I<sup>2</sup>C master.

Figure 21-8. Master Single TRANSMIT

Figure 21-9. Master Single RECEIVE

Figure 21-10. Master TRANSMIT of Multiple Data Bytes

Figure 21-11. Master RECEIVE of Multiple Data Bytes

Figure 21-14. Standard High Speed Mode Master Transmit

### 21.3.6.2 I<sup>2</sup>C Slave Command Sequences

Figure 21-15 on page 1408 presents the command sequence available for the I<sup>2</sup>C slave.

**Figure 21-15. Slave Command Sequence**

## 21.4 Initialization and Configuration

### 21.4.1 Configure the I<sup>2</sup>C Module to Transmit a Single Byte as a Master

The following example shows how to configure the I<sup>2</sup>C module to transmit a single byte as a master. This assumes the system clock is 20 MHz.

1. Enable the I<sup>2</sup>C clock using the **RCGCI2C** register in the System Control module (see page 389).
2. Enable the clock to the appropriate GPIO module via the **RCGCGPIO** register in the System Control module (see page 380). To find out which GPIO port to enable, refer to Table 28-5 on page 1693.
3. In the GPIO module, enable the appropriate pins for their alternate function using the **GPIOAFSEL** register (see page 762). To determine which GPIOs to configure, see Table 28-4 on page 1680.

4. Enable the I2CSDA pin for open-drain operation. See page 767.
5. Configure the PMC<sub>n</sub> fields in the GPIOCTL register to assign the I<sup>2</sup>C signals to the appropriate pins. See page 779 and Table 28-5 on page 1693.
6. Initialize the I<sup>2</sup>C Master by writing the I2CMCR register with a value of 0x0000.0010.
7. Set the desired SCL clock speed of 100 Kbps by writing the I2CMTPR register with the correct value. The value written to the I2CMTPR register represents the number of system clock periods in one SCL clock period. The TPR value is determined by the following equation:

$$\begin{aligned} \text{TPR} &= (\text{System Clock} / (2 * (\text{SCL\_LP} + \text{SCL\_HP}) * \text{SCL\_CLK})) - 1; \\ \text{TPR} &= (20\text{MHz} / (2 * (6+4) * 100000)) - 1; \\ \text{TPR} &= 9 \end{aligned}$$

Write the I2CMTPR register with the value of 0x0000.0009.

8. Specify the slave address of the master and that the next operation is a Transmit by writing the I2CMSA register with a value of 0x0000.0076. This sets the slave address to 0x3B.
9. Place data (byte) to be transmitted in the data register by writing the I2CMDR register with the desired data.
10. Initiate a single byte transmit of the data from Master to Slave by writing the I2CMCS register with a value of 0x0000.0007 (STOP, START, RUN).
11. Wait until the transmission completes by polling the I2CMCS register's BUSBSY bit until it has been cleared.
12. Check the ERROR bit in the I2CMCS register to confirm the transmit was acknowledged.

#### 21.4.2 Configure the I<sup>2</sup>C Master to High Speed Mode

To configure the I<sup>2</sup>C master to High Speed mode:

1. Enable the I<sup>2</sup>C clock using the RCGCI2C register in the System Control module (see page 389).
2. Enable the clock to the appropriate GPIO module via the RCGCGPIO register in the System Control module (see page 380). To find out which GPIO port to enable, refer to Table 28-5 on page 1693.
3. In the GPIO module, enable the appropriate pins for their alternate function using the GPIOAFSEL register (see page 762). To determine which GPIOs to configure, see Table 28-4 on page 1680.
4. Enable the I2CSDA pin for open-drain operation. See page 767.
5. Configure the PMC<sub>n</sub> fields in the GPIOCTL register to assign the I<sup>2</sup>C signals to the appropriate pins. See page 779 and Table 28-5 on page 1693.
6. Initialize the I<sup>2</sup>C Master by writing the I2CMCR register with a value of 0x0000.0010.
7. Set the desired SCL clock speed of 3.33 Mbps by writing the I2CMTPR register with the correct value. The value written to the I2CMTPR register represents the number of system clock periods in one SCL clock period. The TPR value is determined by the following equation:

```
TPR = (System Clock / (2 * (SCL_LP + SCL_HP) * SCL_CLK)) - 1;  
TPR = (80 MHz / (2 * (2 + 1) * 3330000)) - 1;  
TPR = 3
```

Write the **I2CMTPR** register with the value of 0x0000.0003.

8. To send the master code byte, software should place the value of the master code byte into the I2CMSA register and write the I2CMCS register with the following value depending on the required operation:
  - For Standard High-Speed mode, the **I2CMCS** register should be written with 0x13.
  - For Burst High-Speed mode, the **I2CMCS** register should be written with 0x50.
9. This places the I2C master peripheral in High-speed mode, and all subsequent transfers (until STOP) are carried out at High-speed data rate using the normal **I2CMCS** command bits, without setting the HS bit in the **I2CMCS** register.
10. The transaction is ended by setting the STOP bit in the **I2CMCS** register.
11. Wait until the transmission completes by polling the **I2CMCS** register's BUSBSY bit until it has been cleared.
12. Check the ERROR bit in the **I2CMCS** register to confirm the transmit was acknowledged.

## 21.5 Register Map

Table 21-4 on page 1411 lists the I<sup>2</sup>C registers. All addresses given are relative to the I<sup>2</sup>C base address:

- I<sup>2</sup>C 0: 0x4002.0000
- I<sup>2</sup>C 1: 0x4002.1000
- I<sup>2</sup>C 2: 0x4002.2000
- I<sup>2</sup>C 3: 0x4002.3000
- I<sup>2</sup>C 4: 0x400C.0000
- I<sup>2</sup>C 5: 0x400C.1000
- I<sup>2</sup>C 6: 0x400C.2000
- I<sup>2</sup>C 7: 0x400C.3000
- I<sup>2</sup>C 8: 0x400B.8000
- I<sup>2</sup>C 9: 0x400B.9000

Note that the I<sup>2</sup>C module clock must be enabled before the registers can be programmed (see page 389). There must be a delay of 3 system clocks after the I<sup>2</sup>C module clock is enabled before any I<sup>2</sup>C module registers are accessed.

The hw\_i2c.h file in the TivaWare™ Driver Library uses a base address of 0x800 for the I<sup>2</sup>C slave registers. Be aware when using registers with offsets between 0x800 and 0x818 that TivaWare™ for C Series uses an offset between 0x000 and 0x018 with the slave base address.

Table 21-4. Inter-Integrated Circuit (I<sup>2</sup>C) Interface Register Map

| Offset                                   | Name          | Type | Reset       | Description                        | See page |

## **21.6 Register Descriptions (I<sup>2</sup>C Master)**

The remainder of this section lists and describes the I<sup>2</sup>C master registers, in numerical order by address offset.

**Register 1: I<sup>2</sup>C Master Slave Address (I2CMSA), offset 0x000**

This register consists of eight bits: seven address bits (A6-A0), and a Receive/Send bit, which determines if the next operation is a Receive (High), or Transmit (Low).

**I2C Master Slave Address (I2CMSA)**

I2C 0 base: 0x4002.0000  
 I2C 1 base: 0x4002.1000  
 I2C 2 base: 0x4002.2000  
 I2C 3 base: 0x4002.3000  
 I2C 4 base: 0x400C.0000  
 I2C 5 base: 0x400C.1000  
 I2C 6 base: 0x400C.2000  
 I2C 7 base: 0x400C.3000

## Register 2: I<sup>2</sup>C Master Control/Status (I2CMCS), offset 0x004

This register accesses status bits when read and control bits when written. When read, the status register indicates the state of the I<sup>2</sup>C bus controller. When written, the control register configures the I<sup>2</sup>C controller operation.

The **START** bit generates the START or REPEATED START condition. The **STOP** bit determines if the cycle stops at the end of the data cycle or continues to the next transfer cycle, which could be a repeated START. To generate a single transmit cycle, the **I<sup>2</sup>C Master Slave Address (I2CMSA)** register is written with the desired address, the **R/S** bit is cleared, and this register is written with **ACK=X** (0 or 1), **STOP=1**, **START=1**, and **RUN=1** to perform the operation and stop. When the operation is completed (or aborted due an error), an interrupt becomes active and the data may be read from the **I2CMDR** register. When the I<sup>2</sup>C module operates in Master receiver mode, the **ACK** bit is normally set, causing the I<sup>2</sup>C bus controller to transmit an acknowledge automatically after each byte. This bit must be cleared when the I<sup>2</sup>C bus controller requires no further data to be transmitted from the slave transmitter.

|   | 1         | 1           | 0     | 0  | 0   | 0    | 1     | 1   | 0  | Repeated START condition followed by N FIFO-serviced RECEIVE operations and STOP condition (master goes to Idle state).                                   |
|   | 1         | 1           | 0     | 0  | 0   | 1    | 0     | 1   | 0  | Repeated START condition followed by N FIFO-serviced RECEIVE operations (master remains in Master Receive state).   |
|   | 0         | 0           | 0     | 0  | 0   | X    | 0     | 1   | 1  | Repeated START condition followed by TRANSMIT (master goes to Master Transmit state).   |
|   | 0         | 0           | 0     | 0  | 0   | X    | 1     | 1   | 1  | Repeated START condition followed by TRANSMIT and STOP condition (master goes to Idle state).   |
|   | 0         | 1           | 0     | 0  | 0   | X    | 0     | 1   | 0  | Repeated START condition followed by N FIFO-serviced TRANSMIT operations (master goes to Master Transmit state).  |
|   | 0         | 1           | 0     | 0  | 0   | X    | 1     | 1   | 0  | Repeated START condition followed by N FIFO-serviced TRANSMIT operations and STOP condition (master goes to Idle state).                                  |
| All other combinations not listed are non-operations. |           |             |       |    |     |      |       |     | NOP.   |   |

a. An X in a table cell indicates the bit can be 0 or 1.

- b. In Master Receive mode, a STOP condition should be generated only after a Data Negative Acknowledge executed by the master or an Address Negative Acknowledge executed by the slave.

### Register 3: I<sup>2</sup>C Master Data (I2CMDR), offset 0x008

**Important:** This register is read-sensitive. See the register description for details.

This register contains the data to be transmitted when in the Master Transmit state and the data received when in the Master Receive state. If the `BURST` bit is enabled in the `I2CMCS` register, then the `I2CFIFODATA` register is used for the current data transmit or receive value and this register is ignored.

### Register 10: I<sup>2</sup>C Master Clock Low Timeout Count (I2CMCLKOCNT), offset 0x024

This register contains the upper 8 bits of a 12-bit counter that can be used to keep the timeout limit for clock stretching by a remote slave. The lower four bits of the counter are not user visible and are always 0x0.

**Note:** The Master Clock Low Timeout counter counts for the entire time SCL is held Low continuously. If SCL is deasserted at any point, the Master Clock Low Timeout Counter is reloaded with the value in the I2CMCLKOCNT register and begins counting down from this value.

| 7:0       | CNTL     | RW   | 0         | I <sup>2</sup> C Burst Length<br>This field contains the programmed length of bytes of the Burst Transaction. If BURST is enabled this register must be set to a non-zero value otherwise an error will occur. |

### Register 13: I<sup>2</sup>C Master Burst Count (I2CMBCNT), offset 0x034

When BURST is active, the value in the I2CMBLEN register is copied into this register and decremented during the BURST transaction. This register can be used to determine the number of transfers that occurred when a BURST terminates early (as a result of a data NACK). When a BURST completes successfully, this register will contain 0.

Once this bit has been set, it should not be set again unless it has been cleared by writing a 0 or by a reset, otherwise transfer failures may occur.

### Register 16: I<sup>2</sup>C Slave Data (I2CSDR), offset 0x808

**Important:** This register is read-sensitive. See the register description for details.

This register contains the data to be transmitted when in the Slave Transmit state, and the data received when in the Slave Receive state. If the **RXFIFO** bit or **TXFIFO** bit are enabled in the **I2CCSR** register, then this register is ignored and the data value being transferred from the FIFO is contained in the **I2CFIFODATA** register.

**Note:** Best practice recommends that an application should not switch between the **I2CSDR** register and TX FIFO or vice versa for successive transactions.

## Register 22: I<sup>2</sup>C Slave ACK Control (I2CSACKCTL), offset 0x820

This register enables the I<sup>2</sup>C slave to NACK for invalid data or command or ACK for valid data or command. The I<sup>2</sup>C clock is pulled low after the last data bit until this register is written.

## 21.8 Register Descriptions (I<sup>2</sup>C Status and Control)

The remainder of this section lists and describes the I<sup>2</sup>C status and control registers, in numerical order by address offset.

**Register 23: I<sup>2</sup>C FIFO Data (I2CFIFODATA), offset 0xF00**

The I<sup>2</sup>C FIFO Data (I2CFIFODATA) register contains the current value of the top of the RX or TX FIFO stack being used in the a transfer.

**Read-Only Status Register****I2C FIFO Data (I2CFIFODATA)**

I2C 0 base: 0x4002.0000  
 I2C 1 base: 0x4002.1000  
 I2C 2 base: 0x4002.2000

## Register 27: I<sup>2</sup>C Peripheral Configuration (I2CPC), offset 0xFC4

The I2CPC register allows software to enable features present in the I<sup>2</sup>C module.

### I2C Peripheral Configuration (I2CPC)

I2C 0 base: 0x4002.0000  
 I2C 1 base: 0x4002.1000  
 I2C 2 base: 0x4002.2000  
 I2C 3 base: 0x4002.3000  
 I2C 4 base: 0x400C.0000  
 I2C 5 base: 0x400C.1000  
 I2C 6 base: 0x400C.2000  
 I2C 7 base: 0x400C.3000  
 I2C 8 base: 0x400B.8000  
 I2C 9 base: 0x400B.9000  
 Offset 0xFC4  
 Type RO, reset 0x0000.0001

| Bit/Field | Name     | Type | Reset | Description   |
|-----------|----------|------|-------|---|
| 31:1      | reserved | RO   | 0     | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 0         | HS       | RW   | 1     | High-Speed Capable  |

Value Description

| Value | Description   |
|-------|---|
| 0     | The interface is set to Standard, Fast or Fast mode plus operation.   |
| 1     | The interface is set to High-Speed operation. Note that this encoding may only be used if the HS bit in the I2CPP register is set. Otherwise, this encoding is not available. |

## 22 Controller Area Network (CAN) Module

Controller Area Network (CAN) is a multicast, shared serial bus standard for connecting electronic control units (ECUs). CAN was specifically designed to be robust in electromagnetically-noisy environments and can utilize a differential balanced line like RS-485 or a more robust twisted-pair wire. Originally created for automotive purposes, it is also used in many embedded control applications (such as industrial and medical). Bit rates up to 1 Mbps are possible at network lengths less than 40 meters. Decreased bit rates allow longer network distances (for example, 125 Kbps at 500 meters).

The TM4C129CNCZAD microcontroller includes two CAN units with the following features:

- CAN protocol version 2.0 part A/B
- Bit rates up to 1 Mbps
- 32 message objects with individual identifier masks
- Maskable interrupt
- Disable Automatic Retransmission mode for Time-Triggered CAN (TTCAN) applications
- Programmable loopback mode for self-test operation
- Programmable FIFO mode enables storage of multiple message objects
- Gluelessly attaches to an external CAN transceiver through the `CANnTX` and `CANnRX` signals

## 22.1 Block Diagram

Figure 22-1. CAN Controller Block Diagram

## 22.2 Signal Description

The following table lists the external signals of the CAN controller and describes the function of each. The CAN controller signals are alternate functions for some GPIO signals and default to be GPIO signals at reset. The column in the table below titled "Pin Mux/Pin Assignment" lists the possible GPIO pin placements for the CAN signals. The `AFSEL` bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 762) should be set to choose the CAN controller function. The number in parentheses is the encoding that must be programmed into the `PMCn` field in the **GPIO Port Control (GPIOCTL)** register (page 779) to assign the CAN signal to the specified GPIO port pin. For more information on configuring GPIOs, see "General-Purpose Input/Outputs (GPIOs)" on page 731.

**Table 22-1. Controller Area Network Signals (212BGA)**

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type | Description            |

## 22.3 Functional Description

The TM4C129CNCZAD CAN controller conforms to the CAN protocol version 2.0 (parts A and B). Message transfers that include data, remote, error, and overload frames with an 11-bit identifier (standard) or a 29-bit identifier (extended) are supported. Transfer rates can be programmed up to 1 Mbps.

The CAN module consists of three major parts:

- CAN protocol controller and message handler
- Message memory
- CAN register interface

A data frame contains data for transmission, whereas a remote frame contains no data and is used to request the transmission of a specific message object. The CAN data/remote frame is constructed as shown in Figure 22-2.

**Figure 22-2. CAN Data/Remote Frame**

The protocol controller transfers and receives the serial data from the CAN bus and passes the data on to the message handler. The message handler then loads this information into the appropriate message object based on the current filtering and identifiers in the message object memory. The message handler is also responsible for generating interrupts based on events on the CAN bus.

The message object memory is a set of 32 identical memory blocks that hold the current configuration, status, and actual data for each message object. These memory blocks are accessed via either of the CAN message object register interfaces.

The message memory is not directly accessible in the TM4C129CNCZAD memory map, so the TM4C129CNCZAD CAN controller provides an interface to communicate with the message memory via two CAN interface register sets for communicating with the message objects. These two interfaces must be used to read or write to each message object. The two message object interfaces allow parallel access to the CAN controller message objects when multiple objects may have new information that must be processed. In general, one interface is used for transmit data and one for receive data.

### 22.3.1 Initialization

To use the CAN controller, the peripheral clock must be enabled using the **RCGC0** register (see page 392). In addition, the clock to the appropriate GPIO module must be enabled via the **RCGC2** register (see page 392). To find out which GPIO port to enable, refer to Table 28-4 on page 1680. Set the GPIO **AFSEL** bits for the appropriate pins (see page 762). Configure the **PMCn** fields in the **GPIOCTL** register to assign the CAN signals to the appropriate pins. See page 779 and Table 28-5 on page 1693.

Software initialization is started by setting the **INIT** bit in the **CAN Control (CANCTL)** register (with software or by a hardware reset) or by going bus-off, which occurs when the transmitter's error counter exceeds a count of 255. While **INIT** is set, all message transfers to and from the CAN bus are stopped and the **CANnTX** signal is held High. Entering the initialization state does not change the configuration of the CAN controller, the message objects, or the error counters. However, some configuration registers are only accessible while in the initialization state.

To initialize the CAN controller, set the **CAN Bit Timing (CANBIT)** register and configure each message object. If a message object is not needed, label it as not valid by clearing the **MSGVAL** bit in the **CAN IFn Arbitration 2 (CANIFnARB2)** register. Otherwise, the whole message object must be initialized, as the fields of the message object may not have valid information, causing unexpected results. Both the **INIT** and **CCE** bits in the **CANCTL** register must be set in order to access the **CANBIT** register and the **CAN Baud Rate Prescaler Extension (CANBRPE)** register to configure the bit timing. To leave the initialization state, the **INIT** bit must be cleared. Afterwards, the internal Bit Stream Processor (BSP) synchronizes itself to the data transfer on the CAN bus by waiting for the occurrence of a sequence of 11 consecutive recessive bits (indicating a bus idle condition) before it takes part in bus activities and starts message transfers. Message object initialization does not require the CAN to be in the initialization state and can be done on the fly. However, message objects should all be configured to particular identifiers or set to not valid before message transfer starts. To change the configuration of a message object during normal operation, clear the **MSGVAL** bit in the **CANIFnARB2** register to indicate that the message object is not valid during the change. When the configuration is completed, set the **MSGVAL** bit again to indicate that the message object is once again valid.

### 22.3.2 Operation

Two sets of CAN Interface Registers (**CANIF1x** and **CANIF2x**) are used to access the message objects in the Message RAM. The CAN controller coordinates transfers to and from the Message RAM to and from the registers. The two sets are independent and identical and can be used to

queue transactions. Generally, one interface is used to transmit data and one is used to receive data.

Once the CAN module is initialized and the `INIT` bit in the **CANCTL** register is cleared, the CAN module synchronizes itself to the CAN bus and starts the message transfer. As each message is received, it goes through the message handler's filtering process, and if it passes through the filter, is stored in the message object specified by the `MNUM` bit in the **CAN IFn Command Request (CANIFnCRQ)** register. The whole message (including all arbitration bits, data-length code, and eight data bytes) is stored in the message object. If the Identifier Mask (the `MSK` bits in the **CAN IFn Mask 1** and **CAN IFn Mask 2 (CANIFnMSKn)** registers) is used, the arbitration bits that are masked to "don't care" may be overwritten in the message object.

The CPU may read or write each message at any time via the CAN Interface Registers. The message handler guarantees data consistency in case of concurrent accesses.

The transmission of message objects is under the control of the software that is managing the CAN hardware. Message objects can be used for one-time data transfers or can be permanent message objects used to respond in a more periodic manner. Permanent message objects have all arbitration and control set up, and only the data bytes are updated. At the start of transmission, the appropriate `TXRQST` bit in the **CAN Transmission Request n (CANTXRQn)** register and the `NEWDAT` bit in the **CAN New Data n (CANNWDAn)** register are set. If several transmit messages are assigned to the same message object (when the number of message objects is not sufficient), the whole message object has to be configured before the transmission of this message is requested.

The transmission of any number of message objects may be requested at the same time; they are transmitted according to their internal priority, which is based on the message identifier (`MNUM`) for the message object, with 1 being the highest priority and 32 being the lowest priority. Messages may be updated or set to not valid any time, even when their requested transmission is still pending. The old data is discarded when a message is updated before its pending transmission has started. Depending on the configuration of the message object, the transmission of a message may be requested autonomously by the reception of a remote frame with a matching identifier.

Transmission can be automatically started by the reception of a matching remote frame. To enable this mode, set the `RMTEEN` bit in the **CAN IFn Message Control (CANIFnMCTL)** register. A matching received remote frame causes the `TXRQST` bit to be set, and the message object automatically transfers its data or generates an interrupt indicating a remote frame was requested. A remote frame can be strictly a single message identifier, or it can be a range of values specified in the message object. The CAN mask registers, **CANIFnMSKn**, configure which groups of frames are identified as remote frame requests. The `UMASK` bit in the **CANIFnMCTL** register enables the `MSK` bits in the **CANIFnMSKn** register to filter which frames are identified as a remote frame request. The `MXTD` bit in the **CANIFnMSK2** register should be set if a remote frame request is expected to be triggered by 29-bit extended identifiers.

### 22.3.3 Transmitting Message Objects

If the internal transmit shift register of the CAN module is ready for loading, and if a data transfer is not occurring between the CAN Interface Registers and message RAM, the valid message object with the highest priority that has a pending transmission request is loaded into the transmit shift register by the message handler and the transmission is started. The message object's `NEWDAT` bit in the **CANNWDAn** register is cleared. After a successful transmission, and if no new data was written to the message object since the start of the transmission, the `TXRQST` bit in the **CANTXRQn** register is cleared. If the CAN controller is configured to interrupt on a successful transmission of a message object, (the `TXIE` bit in the **CAN IFn Message Control (CANIFnMCTL)** register is set), the `INTPND` bit in the **CANIFnMCTL** register is set after a successful transmission. If the CAN module has lost the arbitration or if an error occurred during the transmission, the message is

re-transmitted as soon as the CAN bus is free again. If, meanwhile, the transmission of a message with higher priority has been requested, the messages are transmitted in the order of their priority.

### 22.3.4 Configuring a Transmit Message Object

The following steps illustrate how to configure a transmit message object.

1. In the **CAN IFn Command Mask (CANIFnCMASK)** register:
  - Set the `WRNRD` bit to specify a write to the **CANIFnCMASK** register; specify whether to transfer the `IDMASK`, `DIR`, and `MXTD` of the message object into the **CAN IFn** registers using the `MASK` bit
  - Specify whether to transfer the `ID`, `DIR`, `XTD`, and `MSGVAL` of the message object into the interface registers using the `ARB` bit
  - Specify whether to transfer the control bits into the interface registers using the `CONTROL` bit
  - Specify whether to clear the `INTPND` bit in the **CANIFnMCTL** register using the `CLRINTPND` bit
  - Specify whether to clear the `NEWDAT` bit in the **CANNWDAn** register using the `NEWDAT` bit
  - Specify which bits to transfer using the `DATAA` and `DATAB` bits
2. In the **CANIFnMSK1** register, use the `MSK[15:0]` bits to specify which of the bits in the 29-bit or 11-bit message identifier are used for acceptance filtering. Note that `MSK[15:0]` in this register are used for bits [15:0] of the 29-bit message identifier and are not used for an 11-bit identifier. A value of 0x00 enables all messages to pass through the acceptance filtering. Also note that in order for these bits to be used for acceptance filtering, they must be enabled by setting the `UMASK` bit in the **CANIFnMCTL** register.
3. In the **CANIFnMSK2** register, use the `MSK[12:0]` bits to specify which of the bits in the 29-bit or 11-bit message identifier are used for acceptance filtering. Note that `MSK[12:0]` are used for bits [28:16] of the 29-bit message identifier; whereas `MSK[12:2]` are used for bits [10:0] of the 11-bit message identifier. Use the `MXTD` and `MDIR` bits to specify whether to use `XTD` and `DIR` for acceptance filtering. A value of 0x00 enables all messages to pass through the acceptance filtering. Also note that in order for these bits to be used for acceptance filtering, they must be enabled by setting the `UMASK` bit in the **CANIFnMCTL** register.
4. For a 29-bit identifier, configure `ID[15:0]` in the **CANIFnARB1** register for bits [15:0] of the message identifier and `ID[12:0]` in the **CANIFnARB2** register for bits [28:16] of the message identifier. Set the `XTD` bit to indicate an extended identifier; set the `DIR` bit to indicate transmit; and set the `MSGVAL` bit to indicate that the message object is valid.
5. For an 11-bit identifier, disregard the **CANIFnARB1** register and configure `ID[12:2]` in the **CANIFnARB2** register for bits [10:0] of the message identifier. Clear the `XTD` bit to indicate a standard identifier; set the `DIR` bit to indicate transmit; and set the `MSGVAL` bit to indicate that the message object is valid.
6. In the **CANIFnMCTL** register:

- Optionally set the `UMASK` bit to enable the mask (`MSK`, `MXTD`, and `MDIR` specified in the **CANIFnMSK1** and **CANIFnMSK2** registers) for acceptance filtering
  - Optionally set the `TXIE` bit to enable the `INTPND` bit to be set after a successful transmission
  - Optionally set the `RMTEN` bit to enable the `TXRQST` bit to be set on the reception of a matching remote frame allowing automatic transmission
  - Set the `EOB` bit for a single message object
  - Configure the `DLC[3:0]` field to specify the size of the data frame. Take care during this configuration not to set the `NEWDAT`, `MSGLST`, `INTPND` or `TXRQST` bits.
7. Load the data to be transmitted into the **CAN IFn Data (CANIFnDA1, CANIFnDA2, CANIFnDB1, CANIFnDB2)** registers. Byte 0 of the CAN data frame is stored in `DATA[7:0]` in the **CANIFnDA1** register.
  8. Program the number of the message object to be transmitted in the `MNUM` field in the **CAN IFn Command Request (CANIFnCRQ)** register.
  9. When everything is properly configured, set the `TXRQST` bit in the **CANIFnMCTL** register. Once this bit is set, the message object is available to be transmitted, depending on priority and bus availability. Note that setting the `RMTEN` bit in the **CANIFnMCTL** register can also start message transmission if a matching remote frame has been received.

### 22.3.5 Updating a Transmit Message Object

The CPU may update the data bytes of a Transmit Message Object any time via the CAN Interface Registers and neither the `MSGVAL` bit in the **CANIFnARB2** register nor the `TXRQST` bits in the **CANIFnMCTL** register have to be cleared before the update.

Even if only some of the data bytes are to be updated, all four bytes of the corresponding **CANIFnDAn/CANIFnDBn** register have to be valid before the content of that register is transferred to the message object. Either the CPU must write all four bytes into the **CANIFnDAn/CANIFnDBn** register or the message object is transferred to the **CANIFnDAn/CANIFnDBn** register before the CPU writes the new data bytes.

In order to only update the data in a message object, the `WRNRD`, `DATAA` and `DATAB` bits in the **CANIFnMSKn** register are set, followed by writing the updated data into **CANIFnDA1**, **CANIFnDA2**, **CANIFnDB1**, and **CANIFnDB2** registers, and then the number of the message object is written to the `MNUM` field in the **CAN IFn Command Request (CANIFnCRQ)** register. To begin transmission of the new data as soon as possible, set the `TXRQST` bit in the **CANIFnMSKn** register.

To prevent the clearing of the `TXRQST` bit in the **CANIFnMCTL** register at the end of a transmission that may already be in progress while the data is updated, the `NEWDAT` and `TXRQST` bits have to be set at the same time in the **CANIFnMCTL** register. When these bits are set at the same time, `NEWDAT` is cleared as soon as the new transmission has started.

### 22.3.6 Accepting Received Message Objects

When the arbitration and control field (the `ID` and `XTD` bits in the **CANIFnARB2** and the `RMTEN` and `DLC[3:0]` bits of the **CANIFnMCTL** register) of an incoming message is completely shifted into the CAN controller, the message handling capability of the controller starts scanning the message RAM for a matching valid message object. To scan the message RAM for a matching message object, the controller uses the acceptance filtering programmed through the mask bits in the **CANIFnMSKn** register and enabled using the `UMASK` bit in the **CANIFnMCTL** register. Each valid

message object, starting with object 1, is compared with the incoming message to locate a matching message object in the message RAM. If a match occurs, the scanning is stopped and the message handler proceeds depending on whether it is a data frame or remote frame that was received.

### 22.3.7 Receiving a Data Frame

The message handler stores the message from the CAN controller receive shift register into the matching message object in the message RAM. The data bytes, all arbitration bits, and the DLC bits are all stored into the corresponding message object. In this manner, the data bytes are connected with the identifier even if arbitration masks are used. The **NEWDAT** bit of the **CANIFnMCTL** register is set to indicate that new data has been received. The CPU should clear this bit when it reads the message object to indicate to the controller that the message has been received, and the buffer is free to receive more messages. If the CAN controller receives a message and the **NEWDAT** bit is already set, the **MSGLST** bit in the **CANIFnMCTL** register is set to indicate that the previous data was lost. If the system requires an interrupt on successful reception of a frame, the **RXIE** bit of the **CANIFnMCTL** register should be set. In this case, the **INTPND** bit of the same register is set, causing the **CANINT** register to point to the message object that just received a message. The **TXRQST** bit of this message object should be cleared to prevent the transmission of a remote frame.

### 22.3.8 Receiving a Remote Frame

A remote frame contains no data, but instead specifies which object should be transmitted. When a remote frame is received, three different configurations of the matching message object have to be considered:

**Table 22-2. Message Object Configurations**

| Configuration in CANIFnMCTL   | Description   |
|---|---|
| <ul style="list-style-type: none"> <li>■ DIR = 1 (direction = transmit); programmed in the <b>CANIFnARB2</b> register</li> <li>■ <b>RMTEN</b> = 1 (set the <b>TXRQST</b> bit of the <b>CANIFnMCTL</b> register at reception of the frame to enable transmission)</li> <li>■ <b>UMASK</b> = 1 or 0</li> </ul>  | At the reception of a matching remote frame, the <b>TXRQST</b> bit of this message object is set. The rest of the message object remains unchanged, and the controller automatically transfers the data in the message object as soon as possible.  |
| <ul style="list-style-type: none"> <li>■ DIR = 1 (direction = transmit); programmed in the <b>CANIFnARB2</b> register</li> <li>■ <b>RMTEN</b> = 0 (do not change the <b>TXRQST</b> bit of the <b>CANIFnMCTL</b> register at reception of the frame)</li> <li>■ <b>UMASK</b> = 0 (ignore mask in the <b>CANIFnMSKn</b> register)</li> </ul>  | At the reception of a matching remote frame, the <b>TXRQST</b> bit of this message object remains unchanged, and the remote frame is ignored. This remote frame is disabled, the data is not transferred and nothing indicates that the remote frame ever happened.   |
| <ul style="list-style-type: none"> <li>■ DIR = 1 (direction = transmit); programmed in the <b>CANIFnARB2</b> register</li> <li>■ <b>RMTEN</b> = 0 (do not change the <b>TXRQST</b> bit of the <b>CANIFnMCTL</b> register at reception of the frame)</li> <li>■ <b>UMASK</b> = 1 (use mask (<b>MSK</b>, <b>MXTD</b>, and <b>MDIR</b> in the <b>CANIFnMSKn</b> register) for acceptance filtering)</li> </ul> | At the reception of a matching remote frame, the <b>TXRQST</b> bit of this message object is cleared. The arbitration and control field ( <b>ID</b> + <b>XTD</b> + <b>RMTEN</b> + <b>DLC</b> ) from the shift register is stored into the message object in the message RAM, and the <b>NEWDAT</b> bit of this message object is set. The data field of the message object remains unchanged; the remote frame is treated similar to a received data frame. This mode is useful for a remote data request from another CAN device for which the TM4C129CNCZAD controller does not have readily available data. The software must fill the data and answer the frame manually. |

### 22.3.9 Receive/Transmit Priority

The receive/transmit priority for the message objects is controlled by the message number. Message object 1 has the highest priority, while message object 32 has the lowest priority. If more than one transmission request is pending, the message objects are transmitted in order based on the message object with the lowest message number. This prioritization is separate from that of the message identifier which is enforced by the CAN bus. As a result, if message object 1 and message object 2 both have valid messages to be transmitted, message object 1 is always transmitted first regardless of the message identifier in the message object itself.

### 22.3.10 Configuring a Receive Message Object

The following steps illustrate how to configure a receive message object.

1. Program the **CAN IFn Command Mask (CANIFnCMASK)** register as described in the “Configuring a Transmit Message Object” on page 1472 section, except that the WRNRD bit is set to specify a write to the message RAM.
2. Program the **CANIFnMSK1** and **CANIFnMSK2** registers as described in the “Configuring a Transmit Message Object” on page 1472 section to configure which bits are used for acceptance filtering. Note that in order for these bits to be used for acceptance filtering, they must be enabled by setting the UMASK bit in the **CANIFnMCTL** register.
3. In the **CANIFnMSK2** register, use the MSK[12:0] bits to specify which of the bits in the 29-bit or 11-bit message identifier are used for acceptance filtering. Note that MSK[12:0] are used for bits [28:16] of the 29-bit message identifier; whereas MSK[12:2] are used for bits [10:0] of the 11-bit message identifier. Use the MXTD and MDIR bits to specify whether to use XTD and DIR for acceptance filtering. A value of 0x00 enables all messages to pass through the acceptance filtering. Also note that in order for these bits to be used for acceptance filtering, they must be enabled by setting the UMASK bit in the **CANIFnMCTL** register.
4. Program the **CANIFnARB1** and **CANIFnARB2** registers as described in the “Configuring a Transmit Message Object” on page 1472 section to program XTD and ID bits for the message identifier to be received; set the MSGVAL bit to indicate a valid message; and clear the DIR bit to specify receive.
5. In the **CANIFnMCTL** register:
  - Optionally set the UMASK bit to enable the mask (MSK, MXTD, and MDIR specified in the **CANIFnMSK1** and **CANIFnMSK2** registers) for acceptance filtering
  - Optionally set the RXIE bit to enable the INTPND bit to be set after a successful reception
  - Clear the RMTEN bit to leave the TXRQST bit unchanged
  - Set the EOB bit for a single message object
  - Configure the DLC[3:0] field to specify the size of the data frame

Take care during this configuration not to set the NEWDAT, MSGLST, INTPND or TXRQST bits.
6. Program the number of the message object to be received in the MNUM field in the **CAN IFn Command Request (CANIFnCRQ)** register. Reception of the message object begins as soon as a matching frame is available on the CAN bus.

When the message handler stores a data frame in the message object, it stores the received Data Length Code and eight data bytes in the **CANIFnDA1**, **CANIFnDA2**, **CANIFnDB1**, and **CANIFnDB2** register. Byte 0 of the CAN data frame is stored in `DATA[7:0]` in the **CANIFnDA1** register. If the Data Length Code is less than 8, the remaining bytes of the message object are overwritten by unspecified values.

The CAN mask registers can be used to allow groups of data frames to be received by a message object. The CAN mask registers, **CANIFnMSKn**, configure which groups of frames are received by a message object. The `UMASK` bit in the **CANIFnMCTL** register enables the `MSK` bits in the **CANIFnMSKn** register to filter which frames are received. The `MXTD` bit in the **CANIFnMSK2** register should be set if only 29-bit extended identifiers are expected by this message object.

### 22.3.11 Handling of Received Message Objects

The CPU may read a received message any time via the CAN Interface registers because the data consistency is guaranteed by the message handler state machine.

Typically, the CPU first writes 0x007F to the **CANIFnCMSK** register and then writes the number of the message object to the **CANIFnCRQ** register. That combination transfers the whole received message from the message RAM into the Message Buffer registers (**CANIFnMSKn**, **CANIFnARBn**, and **CANIFnMCTL**). Additionally, the `NEWDAT` and `INTPND` bits are cleared in the message RAM, acknowledging that the message has been read and clearing the pending interrupt generated by this message object.

If the message object uses masks for acceptance filtering, the **CANIFnARBn** registers show the full, unmasked ID for the received message.

The `NEWDAT` bit in the **CANIFnMCTL** register shows whether a new message has been received since the last time this message object was read. The `MSGLST` bit in the **CANIFnMCTL** register shows whether more than one message has been received since the last time this message object was read. `MSGLST` is not automatically cleared, and should be cleared by software after reading its status.

Using a remote frame, the CPU may request new data from another CAN node on the CAN bus. Setting the `TXRQST` bit of a receive object causes the transmission of a remote frame with the receive object's identifier. This remote frame triggers the other CAN node to start the transmission of the matching data frame. If the matching data frame is received before the remote frame could be transmitted, the `TXRQST` bit is automatically reset. This prevents the possible loss of data when the other device on the CAN bus has already transmitted the data slightly earlier than expected.

#### 22.3.11.1 Configuration of a FIFO Buffer

With the exception of the `EOB` bit in the **CANIFnMCTL** register, the configuration of receive message objects belonging to a FIFO buffer is the same as the configuration of a single receive message object (see “Configuring a Receive Message Object” on page 1475). To concatenate two or more message objects into a FIFO buffer, the identifiers and masks (if used) of these message objects have to be programmed to matching values. Due to the implicit priority of the message objects, the message object with the lowest message object number is the first message object in a FIFO buffer. The `EOB` bit of all message objects of a FIFO buffer except the last one must be cleared. The `EOB` bit of the last message object of a FIFO buffer is set, indicating it is the last entry in the buffer.

#### 22.3.11.2 Reception of Messages with FIFO Buffers

Received messages with identifiers matching to a FIFO buffer are stored starting with the message object with the lowest message number. When a message is stored into a message object of a FIFO buffer, the `NEWDAT` of the **CANIFnMCTL** register bit of this message object is set. By setting

NEWDAT while EOB is clear, the message object is locked and cannot be written to by the message handler until the CPU has cleared the NEWDAT bit. Messages are stored into a FIFO buffer until the last message object of this FIFO buffer is reached. Until all of the preceding message objects have been released by clearing the NEWDAT bit, all further messages for this FIFO buffer are written into the last message object of the FIFO buffer and therefore overwrite previous messages.

### 22.3.11.3 Reading from a FIFO Buffer

When the CPU transfers the contents of a message object from a FIFO buffer by writing its number to the **CANIFnCRQ** register, the **TXRQST** and **CLRINTPND** bits in the **CANIFnCMSK** register should be set such that the **NEWDAT** and **INTPEND** bits in the **CANIFnMCTL** register are cleared after the read. The values of these bits in the **CANIFnMCTL** register always reflect the status of the message object before the bits are cleared. To assure the correct function of a FIFO buffer, the CPU should read out the message objects starting with the message object with the lowest message number. When reading from the FIFO buffer, the user should be aware that a new received message is placed in the message object with the lowest message number for which the **NEWDAT** bit of the **CANIFnMCTL** register is clear. As a result, the order of the received messages in the FIFO is not guaranteed. Figure 22-3 on page 1478 shows how a set of message objects which are concatenated to a FIFO Buffer can be handled by the CPU.

Figure 22-3. Message Objects in a FIFO Buffer

### 22.3.12 Handling of Interrupts

If several interrupts are pending, the **CAN Interrupt (CANINT)** register points to the pending interrupt with the highest priority, disregarding their chronological order. The status interrupt has the highest

priority. Among the message interrupts, the message object's interrupt with the lowest message number has the highest priority. A message interrupt is cleared by clearing the message object's `INTPND` bit in the `CANIFnMCTL` register or by reading the **CAN Status (CANSTS)** register. The status Interrupt is cleared by reading the **CANSTS** register.

The interrupt identifier `INTID` in the **CANINT** register indicates the cause of the interrupt. When no interrupt is pending, the register reads as `0x0000`. If the value of the `INTID` field is different from 0, then an interrupt is pending. If the `IE` bit is set in the **CANCTL** register, the interrupt line to the interrupt controller is active. The interrupt line remains active until the `INTID` field is 0, meaning that all interrupt sources have been cleared (the cause of the interrupt is reset), or until `IE` is cleared, which disables interrupts from the CAN controller.

The `INTID` field of the **CANINT** register points to the pending message interrupt with the highest interrupt priority. The `SIE` bit in the **CANCTL** register controls whether a change of the `RXOK`, `TXOK`, and `LEC` bits in the **CANSTS** register can cause an interrupt. The `EIE` bit in the **CANCTL** register controls whether a change of the `BOFF` and `EWARN` bits in the **CANSTS** register can cause an interrupt. The `IE` bit in the **CANCTL** register controls whether any interrupt from the CAN controller actually generates an interrupt to the interrupt controller. The **CANINT** register is updated even when the `IE` bit in the **CANCTL** register is clear, but the interrupt is not indicated to the CPU.

A value of `0x8000` in the **CANINT** register indicates that an interrupt is pending because the CAN module has updated, but not necessarily changed, the **CANSTS** register, indicating that either an error or status interrupt has been generated. A write access to the **CANSTS** register can clear the `RXOK`, `TXOK`, and `LEC` bits in that same register; however, the only way to clear the source of a status interrupt is to read the **CANSTS** register.

The source of an interrupt can be determined in two ways during interrupt handling. The first is to read the `INTID` bit in the **CANINT** register to determine the highest priority interrupt that is pending, and the second is to read the **CAN Message Interrupt Pending (CANMSGnINT)** register to see all of the message objects that have pending interrupts.

An interrupt service routine reading the message that is the source of the interrupt may read the message and clear the message object's `INTPND` bit at the same time by setting the `CLRINTPND` bit in the **CANIFnCMSK** register. Once the `INTPND` bit has been cleared, the **CANINT** register contains the message number for the next message object with a pending interrupt.

### 22.3.13 Test Mode

A Test Mode is provided which allows various diagnostics to be performed. Test Mode is entered by setting the `TEST` bit in the **CANCTL** register. Once in Test Mode, the `TX[1:0]`, `LBACK`, `SILENT` and `BASIC` bits in the **CAN Test (CANTST)** register can be used to put the CAN controller into the various diagnostic modes. The `RX` bit in the **CANTST** register allows monitoring of the `CANnRX` signal. All **CANTST** register functions are disabled when the `TEST` bit is cleared.

#### 22.3.13.1 Silent Mode

Silent Mode can be used to analyze the traffic on a CAN bus without affecting it by the transmission of dominant bits (Acknowledge Bits, Error Frames). The CAN Controller is put in Silent Mode setting the `SILENT` bit in the **CANTST** register. In Silent Mode, the CAN controller is able to receive valid data frames and valid remote frames, but it sends only recessive bits on the CAN bus and cannot start a transmission. If the CAN Controller is required to send a dominant bit (ACK bit, overload flag, or active error flag), the bit is rerouted internally so that the CAN Controller monitors this dominant bit, although the CAN bus remains in recessive state.

### 22.3.13.2 Loopback Mode

Loopback mode is useful for self-test functions. In Loopback Mode, the CAN Controller internally routes the `CANnTX` signal on to the `CANnRX` signal and treats its own transmitted messages as received messages and stores them (if they pass acceptance filtering) into the message buffer. The CAN Controller is put in Loopback Mode by setting the `LBACK` bit in the **CANTST** register. To be independent from external stimulation, the CAN Controller ignores acknowledge errors (a recessive bit sampled in the acknowledge slot of a data/remote frame) in Loopback Mode. The actual value of the `CANnRX` signal is disregarded by the CAN Controller. The transmitted messages can be monitored on the `CANnTX` signal.

### 22.3.13.3 Loopback Combined with Silent Mode

Loopback Mode and Silent Mode can be combined to allow the CAN Controller to be tested without affecting a running CAN system connected to the `CANnTX` and `CANnRX` signals. In this mode, the `CANnRX` signal is disconnected from the CAN Controller and the `CANnTX` signal is held recessive. This mode is enabled by setting both the `LBACK` and `SILENT` bits in the **CANTST** register.

### 22.3.13.4 Basic Mode

Basic Mode allows the CAN Controller to be operated without the Message RAM. In Basic Mode, The CANIF1 registers are used as the transmit buffer. The transmission of the contents of the IF1 registers is requested by setting the `BUSY` bit of the **CANIF1CRQ** register. The CANIF1 registers are locked while the `BUSY` bit is set. The `BUSY` bit indicates that a transmission is pending. As soon the CAN bus is idle, the CANIF1 registers are loaded into the shift register of the CAN Controller and transmission is started. When the transmission has completed, the `BUSY` bit is cleared and the locked CANIF1 registers are released. A pending transmission can be aborted at any time by clearing the `BUSY` bit in the **CANIF1CRQ** register while the CANIF1 registers are locked. If the CPU has cleared the `BUSY` bit, a possible retransmission in case of lost arbitration or an error is disabled.

The CANIF2 Registers are used as a receive buffer. After the reception of a message, the contents of the shift register are stored in the CANIF2 registers, without any acceptance filtering. Additionally, the actual contents of the shift register can be monitored during the message transfer. Each time a read message object is initiated by setting the `BUSY` bit of the **CANIF2CRQ** register, the contents of the shift register are stored into the CANIF2 registers.

In Basic Mode, all message-object-related control and status bits and of the control bits of the **CANIFnCMSK** registers are not evaluated. The message number of the **CANIFnCRQ** registers is also not evaluated. In the **CANIF2MCTL** register, the `NEWDAT` and `MSGLST` bits retain their function, the `DLC[3:0]` field shows the received DLC, the other control bits are cleared.

Basic Mode is enabled by setting the `BASIC` bit in the **CANTST** register.

### 22.3.13.5 Transmit Control

Software can directly override control of the `CANnTX` signal in four different ways.

- `CANnTX` is controlled by the CAN Controller
- The sample point is driven on the `CANnTX` signal to monitor the bit timing
- `CANnTX` drives a low value
- `CANnTX` drives a high value

The last two functions, combined with the readable CAN receive pin  $CAN_nRX$ , can be used to check the physical layer of the CAN bus.

The Transmit Control function is enabled by programming the  $TX[1:0]$  field in the **CANTST** register. The three test functions for the  $CAN_nTX$  signal interfere with all CAN protocol functions.  $TX[1:0]$  must be cleared when CAN message transfer or Loopback Mode, Silent Mode, or Basic Mode are selected.

### 22.3.14 Bit Timing Configuration Error Considerations

Even if minor errors in the configuration of the CAN bit timing do not result in immediate failure, the performance of a CAN network can be reduced significantly. In many cases, the CAN bit synchronization amends a faulty configuration of the CAN bit timing to such a degree that only occasionally an error frame is generated. In the case of arbitration, however, when two or more CAN nodes simultaneously try to transmit a frame, a misplaced sample point may cause one of the transmitters to become error passive. The analysis of such sporadic errors requires a detailed knowledge of the CAN bit synchronization inside a CAN node and of the CAN nodes' interaction on the CAN bus.

### 22.3.15 Bit Time and Bit Rate

The CAN system supports bit rates in the range of lower than 1 Kbps up to 1000 Kbps. Each member of the CAN network has its own clock generator. The timing parameter of the bit time can be configured individually for each CAN node, creating a common bit rate even though the CAN nodes' oscillator periods may be different.

Because of small variations in frequency caused by changes in temperature or voltage and by deteriorating components, these oscillators are not absolutely stable. As long as the variations remain inside a specific oscillator's tolerance range, the CAN nodes are able to compensate for the different bit rates by periodically resynchronizing to the bit stream.

According to the CAN specification, the bit time is divided into four segments (see Figure 22-4 on page 1482): the Synchronization Segment, the Propagation Time Segment, the Phase Buffer Segment 1, and the Phase Buffer Segment 2. Each segment consists of a specific, programmable number of time quanta (see Table 22-3 on page 1482). The length of the time quantum ( $t_q$ ), which is the basic time unit of the bit time, is defined by the CAN controller's input clock ( $f_{sys}$ ) and the Baud Rate Prescaler (**BRP**):

$$t_q = BRP / f_{sys}$$

The  $f_{sys}$  input clock is the system clock frequency as configured by the **RSCLKCFG** register (see page 276).

The Synchronization Segment Sync is that part of the bit time where edges of the CAN bus level are expected to occur; the distance between an edge that occurs outside of  $Sync$  and the  $Sync$  is called the phase error of that edge.

The Propagation Time Segment Prop is intended to compensate for the physical delay times within the CAN network.

The Phase Buffer Segments Phase1 and Phase2 surround the Sample Point.

The (Re-)Synchronization Jump Width (SJW) defines how far a resynchronization may move the Sample Point inside the limits defined by the Phase Buffer Segments to compensate for edge phase errors.

A given bit rate may be met by different bit-time configurations, but for the proper function of the CAN network, the physical delay times and the oscillator's tolerance range have to be considered.

Figure 22-4. CAN Bit Time

Table 22-3. CAN Protocol Ranges<sup>a</sup>

| Parameter | Range                   | Remark   |
|-----------|-------------------------|--|
| BRP       | [1 .. 64]               | Defines the length of the time quantum t <sub>q</sub> . The <b>CANBRPE</b> register can be used to extend the range to 1024. |
| Sync      | 1 t <sub>q</sub>        | Fixed length, synchronization of bus input to system clock   |
| Prop      | [1 .. 8] t <sub>q</sub> | Compensates for the physical delay times   |
| Phase1    | [1 .. 8] t <sub>q</sub> | May be lengthened temporarily by synchronization   |
| Phase2    | [1 .. 8] t <sub>q</sub> | May be shortened temporarily by synchronization  |
| SJW       | [1 .. 4] t <sub>q</sub> | May not be longer than either Phase Buffer Segment   |

a. This table describes the minimum programmable ranges required by the CAN protocol.

The bit timing configuration is programmed in two register bytes in the **CANBIT** register. In the **CANBIT** register, the four components TSEG2, TSEG1, SJW, and BRP have to be programmed to a numerical value that is one less than its functional value; so instead of values in the range of [1..n], values in the range of [0..n-1] are programmed. That way, for example, SJW (functional range of [1..4]) is represented by only two bits in the SJW bit field. Table 22-4 shows the relationship between the **CANBIT** register values and the parameters.

Table 22-4. CANBIT Register Values

| CANBIT Register Field | Setting           |
|-----------------------|-------------------|
| TSEG2                 | Phase2 - 1        |
| TSEG1                 | Prop + Phase1 - 1 |
| SJW                   | SJW - 1           |
| BRP                   | BRP               |

Therefore, the length of the bit time is (programmed values):

$$[TSEG1 + TSEG2 + 3] \times t_q$$

or (functional values):

$$[Sync + Prop + Phase1 + Phase2] \times t_q$$

The data in the **CANBIT** register is the configuration input of the CAN protocol controller. The baud rate prescaler (configured by the BRP field) defines the length of the time quantum, the basic time

unit of the bit time; the bit timing logic (configured by TSEG1, TSEG2, and SJW) defines the number of time quanta in the bit time.

The processing of the bit time, the calculation of the position of the sample point, and occasional synchronizations are controlled by the CAN controller and are evaluated once per time quantum.

The CAN controller translates messages to and from frames. In addition, the controller generates and discards the enclosing fixed format bits, inserts and extracts stuff bits, calculates and checks the CRC code, performs the error management, and decides which type of synchronization is to be used. The bit value is received or transmitted at the sample point. The information processing time (IPT) is the time after the sample point needed to calculate the next bit to be transmitted on the CAN bus. The IPT includes any of the following: retrieving the next data bit, handling a CRC bit, determining if bit stuffing is required, generating an error flag or simply going idle.

The IPT is application-specific but may not be longer than  $2 t_q$ ; the CAN's IPT is  $0 t_q$ . Its length is the lower limit of the programmed length of Phase2. In case of synchronization, Phase2 may be shortened to a value less than IPT, which does not affect bus timing.

### 22.3.16 Calculating the Bit Timing Parameters

Usually, the calculation of the bit timing configuration starts with a required bit rate or bit time. The resulting bit time (1/bit rate) must be an integer multiple of the system clock period.

The bit time may consist of 4 to 25 time quanta. Several combinations may lead to the required bit time, allowing iterations of the following steps.

The first part of the bit time to be defined is Prop. Its length depends on the delay times measured in the system. A maximum bus length as well as a maximum node delay has to be defined for expandable CAN bus systems. The resulting time for Prop is converted into time quanta (rounded up to the nearest integer multiple of  $t_q$ ).

Sync is  $1 t_q$  long (fixed), which leaves  $(\text{bit time} - \text{Prop} - 1) t_q$  for the two Phase Buffer Segments. If the number of remaining  $t_q$  is even, the Phase Buffer Segments have the same length, that is,  $\text{Phase2} = \text{Phase1}$ , else  $\text{Phase2} = \text{Phase1} + 1$ .

The minimum nominal length of Phase2 has to be regarded as well. Phase2 may not be shorter than the CAN controller's Information Processing Time, which is, depending on the actual implementation, in the range of  $[0..2] t_q$ .

The length of the synchronization jump width is set to the least of 4, Phase1 or Phase2.

The oscillator tolerance range necessary for the resulting configuration is calculated by the formula given below:

$$(1 - df) \times f_{nom} \leq f_{osc} \leq (1 + df) \times f_{nom}$$

where:

- $df$  = Maximum tolerance of oscillator frequency
- $f_{osc}$  = Actual oscillator frequency
- $f_{nom}$  = Nominal oscillator frequency

Maximum frequency tolerance must take into account the following formulas:

$$df \leq \frac{(Phase\_seg1, Phase\_seg2) \min}{2 \times (13 \times t_{bit} - Phase\_Seg2)}$$

$$df \max = 2 \times df \times f_{nom}$$

where:

- Phase1 and Phase2 are from Table 22-3 on page 1482
- t<sub>bit</sub> = Bit Time
- df<sub>max</sub> = Maximum difference between two oscillators

If more than one configuration is possible, that configuration allowing the highest oscillator tolerance range should be chosen.

CAN nodes with different system clocks require different configurations to come to the same bit rate. The calculation of the propagation time in the CAN network, based on the nodes with the longest delay times, is done once for the whole network.

The CAN system's oscillator tolerance range is limited by the node with the lowest tolerance range.

The calculation may show that bus length or bit rate have to be decreased or that the oscillator frequencies' stability has to be increased in order to find a protocol-compliant configuration of the CAN bit timing.

### 22.3.16.1 Example for Bit Timing at High Baud Rate

In this example, the frequency of CAN clock is 25 MHz, and the bit rate is 1 Mbps.

$$\text{bit time} = 1 \mu\text{s} = n * t_q = 5 * t_q$$

$$t_q = 200 \text{ ns}$$

$$t_q = (\text{Baud rate Prescaler}) / \text{CAN Clock}$$

$$\text{Baud rate Prescaler} = t_q * \text{CAN Clock}$$

$$\text{Baud rate Prescaler} = 200\text{E-}9 * 25\text{E}6 = 5$$

$$t_{\text{Sync}} = 1 * t_q = 200 \text{ ns} \quad \backslash\backslash \text{fixed at 1 time quanta}$$

delay of bus driver 50 ns

delay of receiver circuit 30 ns

delay of bus line (40m) 220 ns

$$t_{\text{Prop}} 400 \text{ ns} = 2 * t_q \quad \backslash\backslash 400 \text{ is next integer multiple of } t_q$$

$$\text{bit time} = t_{\text{Sync}} + t_{\text{TSeg1}} + t_{\text{TSeg2}} = 5 * t_q$$

$$\text{bit time} = t_{\text{Sync}} + t_{\text{Prop}} + t_{\text{Phase 1}} + t_{\text{Phase 2}}$$

$$t_{\text{Phase 1}} + t_{\text{Phase 2}} = \text{bit time} - t_{\text{Sync}} - t_{\text{Prop}}$$

$$t_{\text{Phase 1}} + t_{\text{Phase 2}} = (5 * t_q) - (1 * t_q) - (2 * t_q)$$

$$t_{\text{Phase 1}} + t_{\text{Phase 2}} = 2 * t_q$$

$$t_{\text{Phase1}} = 1 * t_q$$

$$t_{\text{Phase2}} = 1 * t_q \quad \backslash\backslash t_{\text{Phase2}} = t_{\text{Phase1}}$$

```

tTSeg1 = tProp + tPhase1
tTSeg1 = (2 * tq) + (1 * tq)
tTSeg1 = 3 * tq

tTSeg2 = tPhase2
tTSeg2 = (Information Processing Time + 1) * tq
tTSeg2 = 1 * tq                \\Assumes IPT=0

tSJW = 1 * tq                \\Least of 4, Phase1 and Phase2

```

In the above example, the bit field values for the **CANBIT** register are:

|       |   |
|-------|---|
| TSEG2 | = TSeg2 -1<br>= 1-1<br>= 0                |
| TSEG1 | = TSeg1 -1<br>= 3-1<br>= 2                |
| SJW   | = SJW -1<br>= 1-1<br>= 0                  |
| BRP   | = Baud rate prescaler - 1<br>= 5-1<br>= 4 |

The final value programmed into the **CANBIT** register = 0x0204.

### 22.3.16.2 Example for Bit Timing at Low Baud Rate

In this example, the frequency of the CAN clock is 50 MHz, and the bit rate is 100 Kbps.

```

bit time = 10 μs = n * tq = 10 * tq
tq = 1 μs
tq = (Baud rate Prescaler)/CAN Clock
Baud rate Prescaler = tq * CAN Clock
Baud rate Prescaler = 1E-6 * 50E6 = 50

tSync = 1 * tq = 1 μs                \\fixed at 1 time quanta

delay of bus driver 200 ns
delay of receiver circuit 80 ns
delay of bus line (40m) 220 ns
tProp 1 μs = 1 * tq                \\1 μs is next integer multiple of tq

bit time = tSync + tTSeg1 + tTSeg2 = 10 * tq
bit time = tSync + tProp + tPhase 1 + tPhase2
tPhase 1 + tPhase2 = bit time - tSync - tProp
tPhase 1 + tPhase2 = (10 * tq) - (1 * tq) - (1 * tq)
tPhase 1 + tPhase2 = 8 * tq
tPhase1 = 4 * tq
tPhase2 = 4 * tq                \\tPhase1 = tPhase2

```

$$\begin{aligned}
 tTSeg1 &= tProp + tPhase1 \\
 tTSeg1 &= (1 * t_q) + (4 * t_q) \\
 tTSeg1 &= 5 * t_q \\
 tTSeg2 &= tPhase2 \\
 tTSeg2 &= (Information Processing Time + 4) * t_q \\
 tTSeg2 &= 4 * t_q \qquad \qquad \qquad \backslash\backslash Assumes IPT=0 \\
 \\ 
 tSJW &= 4 * t_q \qquad \qquad \qquad \backslash\backslash Least of 4, Phase1, and Phase2
 \end{aligned}$$

|       |  |
|-------|--|
| TSEG2 | = TSeg2 -1<br>= 4-1<br>= 3                 |
| TSEG1 | = TSeg1 -1<br>= 5-1<br>= 4                 |
| SJW   | = SJW -1<br>= 4-1<br>= 3                   |
| BRP   | = Baud rate prescaler - 1<br>= 50-1<br>=49 |

The final value programmed into the **CANBIT** register = 0x34F1.

## 22.4 Register Map

Table 22-5 on page 1486 lists the registers. All addresses given are relative to the CAN base address of:

- CAN0: 0x4004.0000
- CAN1: 0x4004.1000

Note that the CAN controller clock must be enabled before the registers can be programmed (see page 392). There must be a delay of 3 system clocks after the CAN module clock is enabled before any CAN module registers are accessed.

**Table 22-5. CAN Register Map**

| Offset | Name      | Type | Reset       | Description                       | See page |
|--------|-----------|------|-------------|-----------------------------------|----------|
| 0x000  | CANCTL    | RW   | 0x0000.0001 | CAN Control                       | 1489     |
| 0x004  | CANSTS    | RW   | 0x0000.0000 | CAN Status                        | 1491     |

## 22.5 CAN Register Descriptions

The remainder of this section lists and describes the CAN registers, in numerical order by address offset. There are two sets of Interface Registers that are used to access the Message Objects in

the Message RAM: **CANIF1x** and **CANIF2x**. The function of the two sets are identical and are used to queue transactions.

## Register 1: CAN Control (CANCTL), offset 0x000

This control register initializes the module and enables test mode and interrupts.

The bus-off recovery sequence (see CAN Specification Rev. 2.0) cannot be shortened by setting or clearing `INIT`. If the device goes bus-off, it sets `INIT`, stopping all bus activities. Once `INIT` has been cleared by the CPU, the device then waits for 129 occurrences of Bus Idle (129 \* 11 consecutive High bits) before resuming normal operations. At the end of the bus-off recovery sequence, the Error Management Counters are reset.

During the waiting time after `INIT` is cleared, each time a sequence of 11 High bits has been monitored, a `BITERROR0` code is written to the **CANSTS** register (the `LEC` field = 0x5), enabling the CPU to readily check whether the CAN bus is stuck Low or continuously disturbed, and to monitor the proceeding of the bus-off recovery sequence.

### CAN Control (CANCTL)

## Register 2: CAN Status (CANSTS), offset 0x004

**Important:** This register is read-sensitive. See the register description for details.

The status register contains information for interrupt servicing such as Bus-Off, error count threshold, and error types.

The LEC field holds the code that indicates the type of the last error to occur on the CAN bus. This field is cleared when a message has been transferred (reception or transmission) without error. The unused error code 0x7 may be written by the CPU to manually set this field to an invalid error so that it can be checked for a change later.

An error interrupt is generated by the BOFF and EWARN bits, and a status interrupt is generated by the RXOK, TXOK, and LEC bits, if the corresponding enable bits in the **CAN Control (CANCTL)** register are set. A change of the EPASS bit or a write to the RXOK, TXOK, or LEC bits does not generate an interrupt.

Reading the **CAN Status (CANSTS)** register clears the **CAN Interrupt (CANINT)** register, if it is pending.

| Value     | Description   |      |        |  |       |             |   |   |   |   |
| 0         | The Receive Error counter is below the Error Passive level (127 or less).       |      |        |  |       |             |   |   |   |   |
| 1         | The Receive Error counter has reached the Error Passive level (128 or greater). |      |        |  |       |             |   |   |   |   |
| 14:8      | REC   | RO   | 0x00   | Receive Error Counter<br>This field contains the state of the receiver error counter (0 to 127).   |       |             |   |   |   |   |
| 7:0       | TEC   | RO   | 0x00   | Transmit Error Counter<br>This field contains the state of the transmit error counter (0 to 255).  |       |             |   |   |   |   |

## Register 4: CAN Bit Timing (CANBIT), offset 0x00C

This register is used to program the bit width and bit quantum. Values are programmed to the system clock frequency. This register is write-enabled by setting the `CCE` and `INIT` bits in the `CANCTL` register. See “Bit Time and Bit Rate” on page 1481 for more information.

### CAN Bit Timing (CANBIT)

CAN0 base: 0x4004.0000  
CAN1 base: 0x4004.1000  
Offset 0x00C  
Type RW, reset 0x0000.2301

|       |          |       |    |    |       |    |    |    |     |    |     |    |    |    |    |    |
|-------|----------|-------|----|----|-------|----|----|----|-----|----|-----|----|----|----|----|----|
|       | 31       | 30    | 29 | 28 | 27    | 26 | 25 | 24 | 23  | 22 | 21  | 20 | 19 | 18 | 17 | 16 |
|       | reserved |       |    |    |       |    |    |    |     |    |     |    |    |    |    |    |
| Type  | RO       | RO    | RO | RO | RO    | RO | RO | RO | RO  | RO | RO  | RO | RO | RO | RO | RO |
| Reset | 0        | 0     | 0  | 0  | 0     | 0  | 0  | 0  | 0   | 0  | 0   | 0  | 0  | 0  | 0  | 0  |
|       | 15       | 14    | 13 | 12 | 11    | 10 | 9  | 8  | 7   | 6  | 5   | 4  | 3  | 2  | 1  | 0  |
|       | reserved | TSEG2 |    |    | TSEG1 |    |    |    | SJW |    | BRP |    |    |    |    |    |
| Type  | RO       | RW    | RW | RW | RW    | RW | RW | RW | RW  | RW | RW  | RW | RW | RW | RW | RW |
| Reset | 0        | 0     | 1  | 0  | 0     | 0  | 1  | 1  | 0   | 0  | 0   | 0  | 0  | 0  | 0  | 1  |

| Bit/Field | Name     | Type | Reset  | Description  |
|-----------|----------|------|--------|--|
| 31:15     | reserved | RO   | 0x0000 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation.  |
| 14:12     | TSEG2    | RW   | 0x2    | Time Segment after Sample Point<br>0x00-0x07: The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.<br>So, for example, the reset value of 0x2 means that 3 (2+1) bit time quanta are defined for <code>Phase2</code> (see Figure 22-4 on page 1482). The bit time quanta is defined by the <code>BRP</code> field.  |
| 11:8      | TSEG1    | RW   | 0x3    | Time Segment Before Sample Point<br>0x00-0x0F: The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.<br>So, for example, the reset value of 0x3 means that 4 (3+1) bit time quanta are defined for <code>Phase1</code> (see Figure 22-4 on page 1482). The bit time quanta is defined by the <code>BRP</code> field.   |
| 7:6       | SJW      | RW   | 0x0    | (Re)Synchronization Jump Width<br>0x00-0x03: The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.<br>During the start of frame (SOF), if the CAN controller detects a phase error (misalignment), it can adjust the length of <code>TSEG2</code> or <code>TSEG1</code> by the value in <code>SJW</code> . So the reset value of 0 adjusts the length by 1 bit time quanta.  |
| 5:0       | BRP      | RW   | 0x1    | Baud Rate Prescaler<br>The value by which the oscillator frequency is divided for generating the bit time quanta. The bit time is built up from a multiple of this quantum.<br>0x00-0x03F: The actual interpretation by the hardware of this value is such that one more than the value programmed here is used.<br><code>BRP</code> defines the number of CAN clock periods that make up 1 bit time quanta, so the reset value is 2 bit time quanta (1+1).<br>The <code>CANBRPE</code> register can be used to further divide the bit time. |

### Register 5: CAN Interrupt (CANINT), offset 0x010

This register indicates the source of the interrupt.

If several interrupts are pending, the **CAN Interrupt (CANINT)** register points to the pending interrupt with the highest priority, disregarding the order in which the interrupts occurred. An interrupt remains pending until the CPU has cleared it. If the **INTID** field is not 0x0000 (the default) and the **IE** bit in the **CANCTL** register is set, the interrupt is active. The interrupt line remains active until the **INTID** field is cleared by reading the **CANSTS** register, or until the **IE** bit in the **CANCTL** register is cleared.

**Note:** Reading the **CAN Status (CANSTS)** register clears the **CAN Interrupt (CANINT)** register, if it is pending.

#### CAN Interrupt (CANINT)

CAN0 base: 0x4004.0000  
 CAN1 base: 0x4004.1000  
 Offset 0x010  
 Type RO, reset 0x0000.0000

## Register 6: CAN Test (CANTST), offset 0x014

This register is used for self-test and external pin access. It is write-enabled by setting the `TEST` bit in the `CANCTL` register. Different test functions may be combined, however, CAN transfers are affected if the `TX` bits in this register are not zero.

|           |          |      |       | 1   | Basic mode is enabled. In basic mode, software should use the <b>CANIF1</b> registers as the transmit buffer and use the <b>CANIF2</b> registers as the receive buffer. |
| 1:0       | reserved | RO   | 0x0   | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |   |

**Register 7: CAN Baud Rate Prescaler Extension (CANBRPE), offset 0x018**

This register is used to further divide the bit time set with the `BRP` bit in the `CANBIT` register. It is write-enabled by setting the `CCE` bit in the `CANCTL` register.

**Register 8: CAN IF1 Command Request (CANIF1CRQ), offset 0x020**

**Register 9: CAN IF2 Command Request (CANIF2CRQ), offset 0x080**

A message transfer is started as soon as there is a write of the message object number to the MNUM field when the TXRQST bit in the CANIF1MCTL register is set. With this write operation, the BUSY bit is automatically set to indicate that a transfer between the CAN Interface Registers and the internal message RAM is in progress. After a wait time of 3 to 6 CAN\_CLK periods, the transfer between the interface register and the message RAM completes, which then clears the BUSY bit.

**Register 10: CAN IF1 Command Mask (CANIF1CMSK), offset 0x024****Register 11: CAN IF2 Command Mask (CANIF2CMSK), offset 0x084**

Reading the Command Mask registers provides status for various functions. Writing to the Command Mask registers specifies the transfer direction and selects which buffer registers are the source or target of the data transfer.

Note that when a read from the message object buffer occurs when the WRNRD bit is clear and the CLRINTPND and/or NEWDAT bits are set, the interrupt pending and/or new data flags in the message object buffer are cleared.

**Register 12: CAN IF1 Mask 1 (CANIF1MSK1), offset 0x028**

**Register 13: CAN IF2 Mask 1 (CANIF2MSK1), offset 0x088**

The mask information provided in this register accompanies the data (**CANIFnDAn**), arbitration information (**CANIFnARBn**), and control information (**CANIFnMCTL**) to the message object in the message RAM. The mask is used with the **ID** bit in the **CANIFnARBn** register for acceptance filtering. Additional mask information is contained in the **CANIFnMSK2** register.

CAN IFn Mask 1 (CANIFnMSK1)

|----|--------|----|---|---------------|
| 15 | MSGVAL | RW | 0 | Message Valid |
|----|--------|----|---|---------------|

| Value | Description   |
|-------|---|
| 0     | The message object is ignored by the message handler.   |
| 1     | The message object is configured and ready to be considered by the message handler within the CAN controller. |

All unused message objects should have this bit cleared during initialization and before clearing the `INIT` bit in the `CANCTL` register. The `MSGVAL` bit must also be cleared before any of the following bits are modified or if the message object is no longer required: the `ID` fields in the `CANIFnARBn` registers, the `XTD` and `DIR` bits in the `CANIFnARB2` register, or the `DLC` field in the `CANIFnMCTL` register.

**Register 30: CAN Transmission Request 1 (CANTXRQ1), offset 0x100**

**Register 31: CAN Transmission Request 2 (CANTXRQ2), offset 0x104**

The **CANTXRQ1** and **CANTXRQ2** registers hold the **TXRQST** bits of the 32 message objects. By reading out these bits, the CPU can check which message object has a transmission request pending. The **TXRQST** bit of a specific message object can be changed by three sources: (1) the CPU via the **CANIFnMCTL** register, (2) the message handler state machine after the reception of a remote frame, or (3) the message handler state machine after a successful transmission.

The **CANTXRQ1** register contains the **TXRQST** bits of the first 16 message objects in the message RAM; the **CANTXRQ2** register contains the **TXRQST** bits of the second 16 message objects.

**Register 32: CAN New Data 1 (CANNWDA1), offset 0x120****Register 33: CAN New Data 2 (CANNWDA2), offset 0x124**

The **CANNWDA1** and **CANNWDA2** registers hold the **NEWDAT** bits of the 32 message objects. By reading these bits, the CPU can check which message object has its data portion updated. The **NEWDAT** bit of a specific message object can be changed by three sources: (1) the CPU via the **CANIFnMCTL** register, (2) the message handler state machine after the reception of a data frame, or (3) the message handler state machine after a successful transmission.

The **CANNWDA1** register contains the **NEWDAT** bits of the first 16 message objects in the message RAM; the **CANNWDA2** register contains the **NEWDAT** bits of the second 16 message objects.

|           |          |      |        | 0        No new data has been written into the data portion of the corresponding message object by the message handler since the last time this flag was cleared by the CPU.                  |
|           |          |      |        | 1        The message handler or the CPU has written new data into the data portion of the corresponding message object.   |

**Register 34: CAN Message 1 Interrupt Pending (CANMSG1INT), offset 0x140**

**Register 35: CAN Message 2 Interrupt Pending (CANMSG2INT), offset 0x144**

The **CANMSG1INT** and **CANMSG2INT** registers hold the **INTPND** bits of the 32 message objects. By reading these bits, the CPU can check which message object has an interrupt pending. The **INTPND** bit of a specific message object can be changed through two sources: (1) the CPU via the **CANIFnMCTL** register, or (2) the message handler state machine after the reception or transmission of a frame.

This field is also encoded in the **CANINT** register.

The **CANMSG1INT** register contains the **INTPND** bits of the first 16 message objects in the message RAM; the **CANMSG2INT** register contains the **INTPND** bits of the second 16 message objects.

**Register 36: CAN Message 1 Valid (CANMSG1VAL), offset 0x160****Register 37: CAN Message 2 Valid (CANMSG2VAL), offset 0x164**

The **CANMSG1VAL** and **CANMSG2VAL** registers hold the **MSGVAL** bits of the 32 message objects. By reading these bits, the CPU can check which message object is valid. The message valid bit of a specific message object can be changed with the **CANIFnARB2** register.

The **CANMSG1VAL** register contains the **MSGVAL** bits of the first 16 message objects in the message RAM; the **CANMSG2VAL** register contains the **MSGVAL** bits of the second 16 message objects in the message RAM.

## 23 Universal Serial Bus (USB) Controller

---

**Important:** The full USB chapter is under NDA. This chapter describes the module features at a high level. For a copy of the full NDA data sheet, follow the instructions in the *Non-Disclosure Agreement for the Tiva C Series TM4C129CNCZAD Microcontroller Data Sheet* (literature number [SPMS415](#)).

---

The TM4C129CNCZAD USB controller operates as a full-speed or low-speed function controller during point-to-point communications with USB Host, Device, or OTG functions. If the integrated ULPI interface is utilized, the USB can operate at high-speed. The controller complies with the USB 2.0 standard, which includes SUSPEND and RESUME signaling. 16 endpoints including two hard-wired for control transfers (one endpoint for IN and one endpoint for OUT) plus 14 endpoints defined by firmware along with a dynamic sizable FIFO support multiple packet queueing. USB DMA access to the FIFO allows minimal interference from system software. Software-controlled connect and disconnect allows flexibility during USB device start-up. The controller complies with OTG Standard's Session Request Protocol (SRP) and Host Negotiation Protocol (HNP).

The TM4C129CNCZAD USB module has the following features:

- Complies with USB-IF (Implementer's Forum) certification standards
- USB 2.0 high-speed (480 Mbps) operation with the integrated ULPI interface communicating with an external PHY
- Link Power Management support which uses link-state awareness to reduce power usage
- 4 transfer types: Control, Interrupt, Bulk, and Isochronous
- 16 endpoints
  - 1 dedicated control IN endpoint and 1 dedicated control OUT endpoint
  - 7 configurable IN endpoints and 7 configurable OUT endpoints
- 4 KB dedicated endpoint memory: one endpoint may be defined for double-buffered 1023-byte isochronous packet size
- VBUS droop detection and interrupt
- Integrated USB DMA with bus master capability
  - Up to eight RX Endpoint channels and up to eight TX Endpoint channels are available.
  - Each channel can be separately programmed to operate in different modes
  - Incremental burst transfers of 4-, 8-, 16- or unspecified length supported

## 23.1 Block Diagram

Figure 23-1. USB Module Block Diagram

## 23.2 Signal Description

The following table lists the external signals of the USB controller and describes the function of each. Some USB controller signals are alternate functions for some GPIO signals and default to be GPIO signals at reset. The column in the table below titled "Pin Mux/Pin Assignment" lists the possible GPIO pin placements for these USB signals. The `AFSEL` bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 762) should be set to choose the USB function. The number in parentheses is the encoding that must be programmed into the `PMCn` field in the **GPIO Port Control (GPIOPCTL)** register (page 779) to assign the USB signal to the specified GPIO port pin. The `USB0VBUS` and `USB0ID` signals are configured by clearing the appropriate `DEN` bit in the **GPIO Digital Enable (GPIODEN)** register. For more information on configuring GPIOs, see "General-Purpose Input/Outputs (GPIOs)" on page 731. The remaining signals (with the word "fixed" in the Pin Mux/Pin Assignment column) have a fixed pin assignment and function.

**Note:** When used in OTG mode, `USB0VBUS` and `USB0ID` do not require any configuration as they are dedicated pins for the USB controller and directly connect to the USB connector's VBUS and ID signals. If the USB controller is used as either a dedicated Host or Device, the `DEVMOD` field in the **USB General-Purpose Control and Status (USBGPCS)** register can be used to connect the `USB0VBUS` and/or `USB0ID` inputs to fixed levels internally, freeing the `PB0` and `PB1` pins for GPIO use. Note that `PB1` (`USB0VBUS`) is a 5-V tolerant signal as required. For proper self-powered Device operation, the VBUS value must still be monitored to assure that if the Host removes VBUS, the self-powered Device disables the D+/D- pull-up resistors. This function can be accomplished by connecting a standard GPIO to VBUS.

The termination resistors for the USB PHY have been added internally, and thus there is no need for external resistors. For a device, there is a 1.5 KOhm pull-up on the D+ and for a host there are 15 KOhm pull-downs on both D+ and D-.

**Note:** Port pins `PL6` and `PL7` operate as Fast GPIO pads, but have 4-mA drive capability only. GPIO register controls for drive strength, slew rate and open drain have no effect on these pins. The registers which have no effect are as follows: **GPIODR2R**, **GPIODR4R**, **GPIODR8R**, **GPIODR12R**, **GPIOSLR**, and **GPIOODR**. Refer to “General-Purpose Input/Outputs (GPIOs)” on page 731 and “Recommended GPIO Operating Characteristics” on page 1707 for more information.

**Table 23-1. USB Signals (212BGA)**

| Pin Name | Pin Number     | Pin Mux / Pin Assignment       | Pin Type | Buffer Type | Description   |
|----------|----------------|--------------------------------|----------|-------------|---|
| USB0CLK  | B17            | PB3 (14)                       | O        | TTL         | 60-MHz clock to the external PHY.   |
| USB0D0   | G16            | PL0 (14)                       | I/O      | TTL         | USB data 0.   |
| USB0D1   | H19            | PL1 (14)                       | I/O      | TTL         | USB data 1.   |
| USB0D2   | G18            | PL2 (14)                       | I/O      | TTL         | USB data 2.   |
| USB0D3   | J18            | PL3 (14)                       | I/O      | TTL         | USB data 3.   |
| USB0D4   | H18            | PL4 (14)                       | I/O      | TTL         | USB data 4.   |
| USB0D5   | G19            | PL5 (14)                       | I/O      | TTL         | USB data 5.   |
| USB0D6   | B12            | PP5 (14)                       | I/O      | TTL         | USB data 6.   |
| USB0D7   | D8             | PP4 (14)                       | I/O      | TTL         | USB data 7.   |
| USB0DIR  | C12            | PP3 (14)                       | O        | TTL         | Indicates that the external PHY is able to accept data from the USB controller.   |
| USB0DM   | B18            | PL7                            | I/O      | Analog      | Bidirectional differential data pin (D- per USB specification) for USB0.  |
| USB0DP   | C18            | PL6                            | I/O      | Analog      | Bidirectional differential data pin (D+ per USB specification) for USB0.  |
| USB0EPEN | V5<br>R7<br>B3 | PA6 (5)<br>PA7 (11)<br>PD6 (5) | O        | TTL         | Optionally used in Host mode to control an external power source to supply power to the USB bus.  |
| USB0ID   | A16            | PB0                            | I        | Analog      | This signal senses the state of the USB ID signal. The USB PHY enables an integrated pull-up, and an external element (USB connector) indicates the initial state of the USB controller (pulled down is the A side of the cable and pulled up is the B side). |
| USB0NXT  | B13            | PP2 (14)                       | O        | TTL         | Asserted by the external PHY to throttle all data types.  |
| USB0PFLT | R7<br>B2       | PA7 (5)<br>PD7 (5)             | I        | TTL         | Optionally used in Host mode by an external power source to indicate an error state by that power source.   |
| USB0STP  | A17            | PB2 (14)                       | O        | TTL         | Asserted by the USB controller to signal the end of a USB transmit packet or register write operation.  |
| USB0VBUS | B16            | PB1                            | I/O      | Analog      | This signal is used during the session request protocol. This signal allows the USB PHY to both sense the voltage level of VBUS, and pull up VBUS momentarily during VBUS pulsing.  |

## 23.3 Register Map

Table 23-2 on page 1521 lists the registers. All addresses given are relative to the USB base address of 0x4005.0000. Note that the USB controller clock must be enabled before the registers can be programmed (see page 391). There must be a delay of 3 system clocks after the USB module clock is enabled before any USB module registers are accessed.

**Note:** Descriptions for all these registers can be found in the NDA version of the data sheet.

**Table 23-2. List of Registers**

| Offset | Name           | Description  |
|--------|----------------|--|

## 24 Analog Comparators

An analog comparator is a peripheral that compares two analog voltages and provides a logical output that signals the comparison result.

**Note:** Not all comparators have the option to drive an output pin. See “Signal Description” on page 1528 for more information.

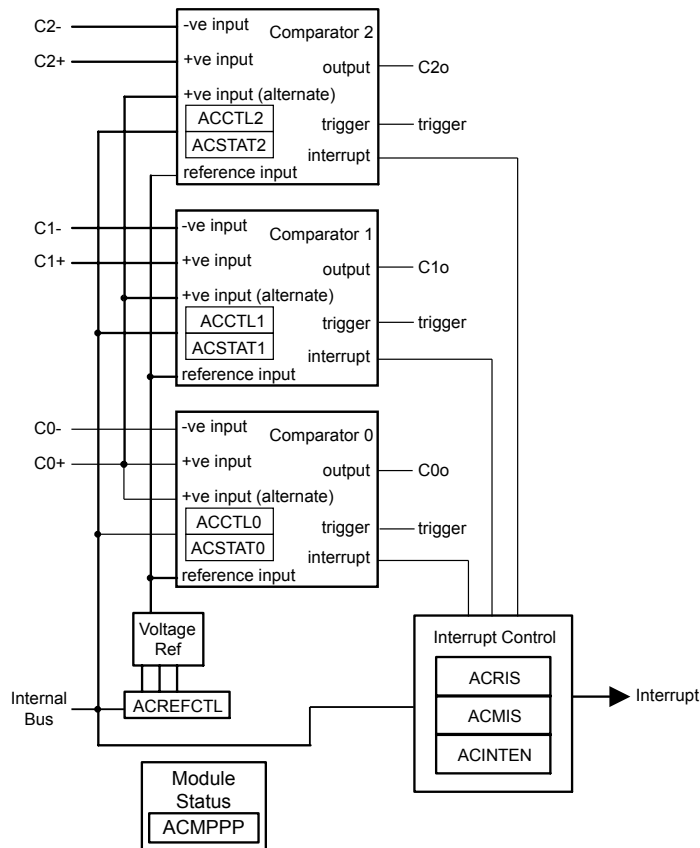

The comparator can provide its output to a device pin, acting as a replacement for an analog comparator on the board. In addition, the comparator can signal the application via interrupts or trigger the start of a sample sequence in the ADC. The interrupt generation and ADC triggering logic is separate and independent. This flexibility means, for example, that an interrupt can be generated on a rising edge and the ADC triggered on a falling edge.

The TM4C129CNCZAD microcontroller provides three independent integrated analog comparators with the following functions:

- Compare external pin input to external pin input or to internal programmable voltage reference
- Compare a test voltage against any one of the following voltages:
  - An individual external reference voltage
  - A shared single external reference voltage
  - A shared internal reference voltage

## 24.1 Block Diagram

Figure 24-1. Analog Comparator Module Block Diagram

**Note:** This block diagram depicts the maximum number of analog comparators and comparator outputs for the family of microcontrollers; the number for this specific device may vary. See page 1541 for what is included on this device.

## 24.2 Signal Description

The following table lists the external signals of the Analog Comparators and describes the function of each. The Analog Comparator output signals are alternate functions for some GPIO signals and default to be GPIO signals at reset. The column in the table below titled "Pin Mux/Pin Assignment" lists the possible GPIO pin placements for the Analog Comparator signals. The `AFSEL` bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 762) should be set to choose the Analog Comparator function. The number in parentheses is the encoding that must be programmed into the `PMCn` field in the **GPIO Port Control (GPIOPCTL)** register (page 779) to assign the Analog Comparator signal to the specified GPIO port pin. The positive and negative input signals are configured by clearing the `DEN` bit in the **GPIO Digital Enable (GPIODEN)** register. For more information on configuring GPIOs, see "General-Purpose Input/Outputs (GPIOs)" on page 731.

Table 24-1. Analog Comparators Signals (212BGA)

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type | Description                         |
|----------|------------|--------------------------|----------|-------------|-------------------------------------|
| C0+      | L2         | PC6                      | I        | Analog      | Analog comparator 0 positive input. |

## 24.3 Functional Description

The comparator compares the VIN- and VIN+ inputs to produce an output, VOUT.

$$VIN- < VIN+, VOUT = 1$$

$$VIN- > VIN+, VOUT = 0$$

As shown in Figure 24-2 on page 1529, the input source for VIN- is an external input, Cn-, where n is the analog comparator number. In addition to an external input, Cn+, input sources for VIN+ can be the C0+ or an internal reference, V<sub>IREF</sub>.

Figure 24-2. Structure of Comparator Unit

A comparator is configured through two status/control registers, **Analog Comparator Control (ACCTL)** and **Analog Comparator Status (ACSTAT)**. The internal reference is configured through one control register, **Analog Comparator Reference Voltage Control (ACREFCTL)**. Interrupt status and control are configured through three registers, **Analog Comparator Masked Interrupt Status (ACMIS)**, **Analog Comparator Raw Interrupt Status (ACRIS)**, and **Analog Comparator Interrupt Enable (ACINTEN)**.

Typically, the comparator output is used internally to generate an interrupt as controlled by the I<sub>SEN</sub> bit in the **ACCTL** register. The output may also be used to drive one of the external pins (C<sub>no</sub>), or generate an analog-to-digital converter (ADC) trigger.

**Important:** The  $ASRCP$  bits in the **ACCTL** register must be set before using the analog comparators.

### 24.3.1 Internal Reference Programming

The structure of the internal reference is shown in Figure 24-3 on page 1530. The internal reference is controlled by a single configuration register (**ACREFCTL**).

**Figure 24-3. Comparator Internal Reference Structure**

**Note:** In the figure above,  $N \cdot R$  represents a multiple of the  $R$  value that produces the results specified in Table 24-2 on page 1530.

The internal reference can be programmed in one of two modes (low range or high range) depending on the  $RNG$  bit in the **ACREFCTL** register. When  $RNG$  is clear, the internal reference is in high-range mode, and when  $RNG$  is set the internal reference is in low-range mode.

In each range, the internal reference,  $V_{IREF}$ , has 16 preprogrammed thresholds or step values. The threshold to be used to compare the external input voltage against is selected using the  $VREF$  field in the **ACREFCTL** register.

In the high-range mode, the  $V_{IREF}$  threshold voltages start at the ideal high-range starting voltage of  $V_{DDA}/4.2$  and increase in ideal constant voltage steps of  $V_{DDA}/29.4$ .

In the low-range mode, the  $V_{IREF}$  threshold voltages start at 0 V and increase in ideal constant voltage steps of  $V_{DDA}/22.12$ . The ideal  $V_{IREF}$  step voltages for each mode and their dependence on the  $RNG$  and  $VREF$  fields are summarized in Table 24-2.

**Table 24-2. Internal Reference Voltage and ACREFCTL Field Values**

| ACREFCTL Register |               | Output Reference Voltage Based on $VREF$ Field Value   |
|-------------------|---------------|--|
| EN Bit Value      | RNG Bit Value |  |
| EN=0              | RNG=X         | 0 V (GND) for any value of $VREF$ . It is recommended that $RNG=1$ and $VREF=0$ to minimize noise on the reference ground. |

**Table 24-2. Internal Reference Voltage and ACREFACTL Field Values (continued)**

| ACREFCTL Register |               | Output Reference Voltage Based on VREF Field Value  |
|-------------------|---------------|---|
| EN Bit Value      | RNG Bit Value |   |
| EN=1              | RNG=0         | <p>V<sub>IREF</sub> High Range: 16 voltage threshold values indexed by VREF = 0x0 .. 0xF<br/> Ideal starting voltage (VREF=0): V<sub>DDA</sub> / 4.2<br/> Ideal step size: V<sub>DDA</sub> / 29.4<br/> Ideal V<sub>IREF</sub> threshold values: V<sub>IREF</sub> (VREF) = V<sub>DDA</sub> / 4.2 + VREF * (V<sub>DDA</sub> / 29.4), for VREF = 0x0 .. 0xF<br/> For minimum and maximum V<sub>IREF</sub> threshold values, see Table 24-3 on page 1531.</p> |
|                   | RNG=1         | <p>V<sub>IREF</sub> Low Range: 16 voltage threshold values indexed by VREF = 0x0 .. 0xF<br/> Ideal starting voltage (VREF=0): 0 V<br/> Ideal step size: V<sub>DDA</sub> / 22.12<br/> Ideal V<sub>IREF</sub> threshold values: V<sub>IREF</sub> (VREF) = VREF * (V<sub>DDA</sub> / 22.12), for VREF = 0x0 .. 0xF<br/> For minimum and maximum V<sub>IREF</sub> threshold values, see Table 24-4 on page 1532.</p>  |

Note that the values shown in Table 24-2 are the ideal values of the V<sub>IREF</sub> thresholds. These values actually vary between minimum and maximum values for each threshold step, depending on process and temperature. The minimum and maximum values for each step are given by:

- V<sub>IREF</sub>(VREF) [Min] = Ideal V<sub>IREF</sub>(VREF) – (Ideal Step size – 2 mV) / 2
- V<sub>IREF</sub>(VREF) [Max] = Ideal V<sub>IREF</sub>(VREF) + (Ideal Step size – 2 mV) / 2

Examples of minimum and maximum V<sub>IREF</sub> values for V<sub>DDA</sub> = 3.3V for high and low ranges, are shown in Table 24-3 and Table 24-4. Note that these examples are only valid for V<sub>DDA</sub> = 3.3V; values scale up and down with V<sub>DDA</sub>.

**Table 24-3. Analog Comparator Voltage Reference Characteristics, V<sub>DDA</sub> = 3.3V, EN= 1, and RNG = 0**

| VREF Value | V <sub>IREF</sub> Min | Ideal V <sub>IREF</sub> | V <sub>IREF</sub> Max | Unit |

## 24.4 Initialization and Configuration

The following example shows how to configure an analog comparator to read back its output value from an internal register.

1. Enable the analog comparator clock by writing a value of 0x0000.0001 to the **RCGCACMP** register in the System Control module (see page 394).
2. Enable the clock to the appropriate GPIO modules via the **RCGCGPIO** register (see page 380). To find out which GPIO ports to enable, refer to Table 28-5 on page 1693.
3. In the GPIO module, enable the GPIO port/pin associated with the input signals as GPIO inputs. To determine which GPIO to configure, see Table 28-4 on page 1680.
4. Configure the  $PMC_n$  fields in the **GPIOPCTL** register to assign the analog comparator output signals to the appropriate pins (see page 779 and Table 28-5 on page 1693).
5. Configure the internal voltage reference to 1.65 V by writing the **ACREFCTL** register with the value 0x0000.030C.
6. Configure the comparator to use the internal voltage reference and to *not* invert the output by writing the **ACCTLn** register with the value of 0x0000.040C.
7. Delay for 10  $\mu$ s.
8. Read the comparator output value by reading the **ACSTATn** register's **OVAL** value.

Change the level of the comparator negative input signal  $C^-$  to see the **OVAL** value change.

## 24.5 Register Map

Table 24-5 on page 1533 lists the comparator registers. The offset listed is a hexadecimal increment to the register's address, relative to the Analog Comparator base address of 0x4003.C000. Note that the analog comparator clock must be enabled before the registers can be programmed (see page 394). There must be a delay of 3 system clocks after the analog comparator module clock is enabled before any analog comparator module registers are accessed.

**Table 24-5. Analog Comparators Register Map**

| Offset | Name     | Type | Reset       | Description                                 | See page |

## 24.6 Register Descriptions

The remainder of this section lists and describes the Analog Comparator registers, in numerical order by address offset.

## Register 1: Analog Comparator Masked Interrupt Status (ACMIS), offset 0x000

This register provides a summary of the interrupt status (masked) of the comparators.

### Analog Comparator Masked Interrupt Status (ACMIS)

Base 0x4003.C000  
 Offset 0x000  
 Type RW1C, reset 0x0000.0000

|       |          |    |    |    |    |    |    |    |    |    |    |    |    |      |      |      |

Clearing this bit also clears the <b>IN0</b> bit in the <b>ACRIS</b> register.</p> |

**Register 2: Analog Comparator Raw Interrupt Status (ACRIS), offset 0x004**

This register provides a summary of the interrupt status (raw) of the comparators. The bits in this register must be enabled to generate interrupts using the **ACINTEN** register.

## 25 Pulse Width Modulator (PWM)

Pulse width modulation (PWM) is a powerful technique for digitally encoding analog signal levels. High-resolution counters are used to generate a square wave, and the duty cycle of the square wave is modulated to encode an analog signal. Typical applications include switching power supplies and motor control.

The TM4C129CNCZAD microcontroller contains one PWM module, with four PWM generator blocks and a control block, for a total of 8 PWM outputs. The control block determines the polarity of the PWM signals, and which signals are passed through to the pins.

Each PWM generator block produces two PWM signals that share the same timer and frequency and can either be programmed with independent actions or as a single pair of complementary signals with dead-band delays inserted. The output signals, `pwmA'` and `pwmB'`, of the PWM generation blocks are managed by the output control block before being passed to the device pins as `MnPWM0` and `MnPWM1` or `MnPWM2` and `MnPWM3`, and so on.

The TM4C129CNCZAD PWM module provides a great deal of flexibility and can generate simple PWM signals, such as those required by a simple charge pump as well as paired PWM signals with dead-band delays, such as those required by a half-H bridge driver. Three generator blocks can also generate the full six channels of gate controls required by a 3-phase inverter bridge.

Each PWM generator block has the following features:

- Four fault-condition handling inputs to quickly provide low-latency shutdown and prevent damage to the motor being controlled
- One 16-bit counter
  - Runs in Down or Up/Down mode
  - Output frequency controlled by a 16-bit load value
  - Load value updates can be synchronized
  - Produces output signals at zero and load value
- Two PWM comparators
  - Comparator value updates can be synchronized
  - Produces output signals on match
- PWM signal generator
  - Output PWM signal is constructed based on actions taken as a result of the counter and PWM comparator output signals
  - Produces two independent PWM signals
- Dead-band generator
  - Produces two PWM signals with programmable dead-band delays suitable for driving a half-H bridge
  - Can be bypassed, leaving input PWM signals unmodified

- Can initiate an ADC sample sequence

The control block determines the polarity of the PWM signals and which signals are passed through to the pins. The output of the PWM generation blocks are managed by the output control block before being passed to the device pins. The PWM control block has the following options:

- PWM output enable of each PWM signal
- Optional output inversion of each PWM signal (polarity control)
- Optional fault handling for each PWM signal
- Synchronization of timers in the PWM generator blocks
- Synchronization of timer/comparator updates across the PWM generator blocks
- Extended PWM synchronization of timer/comparator updates across the PWM generator blocks
- Interrupt status summary of the PWM generator blocks
- Extended PWM fault handling, with multiple fault signals, programmable polarities, and filtering
- PWM generators can be operated independently or synchronized with other generators

## **25.1 Block Diagram**

Figure 25-1 on page 1545 provides the TM4C129CNCZAD PWM module diagram and Figure 25-2 on page 1545 provides a more detailed diagram of a TM4C129CNCZAD PWM generator. The TM4C129CNCZAD controller contains four generator blocks that generate eight independent PWM signals or four paired PWM signals with dead-band delays inserted.

Figure 25-1. PWM Module Diagram

Figure 25-2. PWM Generator Block Diagram

## 25.2 Signal Description

The following table lists the external signals of the PWM module and describes the function of each. The PWM controller signals are alternate functions for some GPIO signals and default to be GPIO signals at reset. The column in the table below titled "Pin Mux/Pin Assignment" lists the possible GPIO pin placements for these PWM signals. The `AFSEL` bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 762) should be set to choose the PWM function. The number in parentheses is the encoding that must be programmed into the `PMCn` field in the **GPIO Port Control (GPIOPTL)** register (page 779) to assign the PWM signal to the specified GPIO port pin. For more information on configuring GPIOs, see "General-Purpose Input/Outputs (GPIOs)" on page 731.

## 25.3 Functional Description

### 25.3.1 Clock Configuration

The PWM has two clock source options:

- The System Clock
- A predivided System Clock

The clock source is selected by programming the `USEPWM` bit in the **PWM Clock Configuration (PWMCC)** register. The `PWMDIV` bitfield specifies the divisor of the System Clock that is used to create the PWM Clock.

### 25.3.2 PWM Timer

The timer in each PWM generator runs in one of two modes: Count-Down mode or Count-Up/Down mode. In Count-Down mode, the timer counts from the load value to zero, goes back to the load value, and continues counting down. In Count-Up/Down mode, the timer counts from zero up to the load value, back down to zero, back up to the load value, and so on. Generally, Count-Down mode is used for generating left- or right-aligned PWM signals, while the Count-Up/Down mode is used for generating center-aligned PWM signals.

The timers output three signals that are used in the PWM generation process: the direction signal (this is always Low in Count-Down mode, but alternates between Low and High in Count-Up/Down mode), a single-clock-cycle-width High pulse when the counter is zero, and a single-clock-cycle-width High pulse when the counter is equal to the load value. Note that in Count-Down mode, the zero pulse is immediately followed by the load pulse. In the figures in this chapter, these signals are labelled "dir," "zero," and "load."

### 25.3.3 PWM Comparators

Each PWM generator has two comparators that monitor the value of the counter; when either comparator matches the counter, they output a single-clock-cycle-width High pulse, labeled "cmpA" and "cmpB" in the figures in this chapter. When in Count-Up/Down mode, these comparators match both when counting up and when counting down, and thus are qualified by the counter direction signal. These qualified pulses are used in the PWM generation process. If either comparator match value is greater than the counter load value, then that comparator never outputs a High pulse.

Figure 25-3 on page 1548 shows the behavior of the counter and the relationship of these pulses when the counter is in Count-Down mode. Figure 25-4 on page 1548 shows the behavior of the counter and the relationship of these pulses when the counter is in Count-Up/Down mode. In these figures, the following definitions apply:

- LOAD is the value in the **PWMnLOAD** register
- COMPA is the value in the **PWMnCMPA** register
- COMPB is the value in the **PWMnCMPB** register
- 0 is the value zero
- load is the internal signal that has a single-clock-cycle-width High pulse when the counter is equal to the load value
- zero is the internal signal that has a single-clock-cycle-width High pulse when the counter is zero
- cmpA is the internal signal that has a single-clock-cycle-width High pulse when the counter is equal to COMPA
- cmpB is the internal signal that has a single-clock-cycle-width High pulse when the counter is equal to COMPB
- dir is the internal signal that indicates the count direction

**Figure 25-3. PWM Count-Down Mode**

**Figure 25-4. PWM Count-Up/Down Mode**

### 25.3.4 PWM Signal Generator

Each PWM generator takes the load, zero, cmpA, and cmpB pulses (qualified by the dir signal) and generates two internal PWM signals, pwmA and pwmB. In Count-Down mode, there are four events that can affect these signals: zero, load, match A down, and match B down. In Count-Up/Down mode, there are six events that can affect these signals: zero, load, match A down, match A up, match B down, and match B up. The match A or match B events are ignored when they coincide with the zero or load events. If the match A and match B events coincide, the first signal, pwmA, is generated based only on the match A event, and the second signal, pwmB, is generated based only on the match B event.

For each event, the effect on each output PWM signal is programmable: it can be left alone (ignoring the event), it can be toggled, it can be driven Low, or it can be driven High. These actions can be used to generate a pair of PWM signals of various positions and duty cycles, which do or do not overlap. Figure 25-5 on page 1549 shows the use of Count-Up/Down mode to generate a pair of center-aligned, overlapped PWM signals that have different duty cycles. This figure shows the pwmA and pwmB signals before they have passed through the dead-band generator.

**Figure 25-5. PWM Generation Example In Count-Up/Down Mode**

In this example, the first generator is set to drive High on match A up, drive Low on match A down, and ignore the other four events. The second generator is set to drive High on match B up, drive Low on match B down, and ignore the other four events. Changing the value of comparator A changes the duty cycle of the pwmA signal, and changing the value of comparator B changes the duty cycle of the pwmB signal.

### 25.3.5 Dead-Band Generator

The pwmA and pwmB signals produced by each PWM generator are passed to the dead-band generator. If the dead-band generator is disabled, the PWM signals simply pass through to the pwmA' and pwmB' signals unmodified. If the dead-band generator is enabled, the pwmB signal is lost and two PWM signals are generated based on the pwmA signal. The first output PWM signal, pwmA' is the pwmA signal with the rising edge delayed by a programmable amount. The second output PWM signal, pwmB', is the inversion of the pwmA signal with a programmable delay added between the falling edge of the pwmA signal and the rising edge of the pwmB' signal.

The resulting signals are a pair of active High signals where one is always High, except for a programmable amount of time at transitions where both are Low. These signals are therefore suitable for driving a half-H bridge, with the dead-band delays preventing shoot-through current from damaging the power electronics. Figure 25-6 on page 1549 shows the effect of the dead-band generator on the pwmA signal and the resulting pwmA' and pwmB' signals that are transmitted to the output control block.

**Figure 25-6. PWM Dead-Band Generator**

### 25.3.6 Interrupt/ADC-Trigger Selector

Each PWM generator also takes the same four (or six) counter events and uses them to generate an interrupt or an ADC trigger. Any of these events or a set of these events can be selected as a source for an interrupt; when any of the selected events occur, an interrupt is generated. Additionally, the same event, a different event, the same set of events, or a different set of events can be selected as a source for an ADC trigger; when any of these selected events occur, an ADC trigger pulse is generated. The selection of events allows the interrupt or ADC trigger to occur at a specific position

within the pwmA or pwmB signal. Note that interrupts and ADC triggers are based on the raw events; delays in the PWM signal edges caused by the dead-band generator are not taken into account.

### 25.3.7 Synchronization Methods

The PWM module provides four PWM generators, each providing two PWM outputs that may be used in a wide variety of applications. Generally speaking, the PWM is used in one of two categories of operation:

- **Unsynchronized.** The PWM generator and its two output signals are used alone, independent of other PWM generators.
- **Synchronized.** The PWM generator and its two outputs signals are used in conjunction with other PWM generators using a common, unified time base. If multiple PWM generators are configured with the same counter load value, synchronization can be used to guarantee that they also have the same count value (the PWM generators must be configured before they are synchronized). With this feature, more than two  $MnPWMn$  signals can be produced with a known relationship between the edges of those signals because the counters always have the same values. Other states in the module provide mechanisms to maintain the common time base and mutual synchronization.

The counter in a PWM generator can be reset to zero by writing the **PWM Time Base Sync (PWMSYNC)** register and setting the  $SYNCn$  bit associated with the generator. Multiple PWM generators can be synchronized together by setting all necessary  $SYNCn$  bits in one access. For example, setting the  $SYNC0$  and  $SYNC1$  bits in the **PWMSYNC** register causes the counters in PWM generators 0 and 1 to reset together.

Additional synchronization can occur between multiple PWM generators by updating register contents in one of the following three ways:

- **Immediately.** The write value has immediate effect, and the hardware reacts immediately.
- **Locally Synchronized.** The write value does not affect the logic until the counter reaches the value zero at the end of the PWM cycle. In this case, the effect of the write is deferred, providing a guaranteed defined behavior and preventing overly short or overly long output PWM pulses.
- **Globally Synchronized.** The write value does not affect the logic until two sequential events have occurred: (1) the Update mode for the generator function is programmed for global synchronization in the **PWMnCTL** register, and (2) the counter reaches zero at the end of the PWM cycle. In this case, the effect of the write is deferred until the end of the PWM cycle following the end of all updates. This mode allows multiple items in multiple PWM generators to be updated simultaneously without odd effects during the update; everything runs from the old values until a point at which they all run from the new values. The Update mode of the load and comparator match values can be individually configured in each PWM generator block. It typically makes sense to use the synchronous update mechanism across PWM generator blocks when the timers in those blocks are synchronized, although this is not required in order for this mechanism to function properly.

The following registers provide either local or global synchronization based on the state of various Update mode bits and fields in the **PWMnCTL** register ( $LOADUPD$ ;  $CMPAUPD$ ;  $CMPBUPD$ ):

- Generator Registers: **PWMnLOAD**, **PWMnCMPA**, and **PWMnCMPB**

The following registers default to immediate update, but are provided with the optional functionality of synchronously updating rather than having all updates take immediate effect:

- Module-Level Register: **PWMENABLE** (based on the state of the `ENUPDn` bits in the `PWMENUPD` register).
- Generator Register: **PWMnGENA**, **PWMnGENB**, **PWMnDBCTL**, **PWMnDBRISE**, and **PWMnDBFALL** (based on the state of various Update mode bits and fields in the `PWMnCTL` register (`GENAUPD`; `GENBUPD`; `DBCTLUPD`; `DBRISEUPD`; `DBFALLUPD`)).

All other registers are considered statically provisioned for the execution of an application or are used dynamically for purposes unrelated to maintaining synchronization and therefore do not need synchronous update functionality.

### 25.3.8 Fault Conditions

A fault condition is one in which the controller must be signaled to stop normal PWM function and then set the `MnPWMn` signals to a safe state. Two basic situations cause fault conditions:

- The microcontroller is stalled and cannot perform the necessary computation in the time required for motion control
- An external error or event is detected

The PWM generator can use the following inputs to generate a fault condition, including:

- `MnFAULTn` pin assertion
- A stall of the controller generated by the debugger
- The trigger of an ADC digital comparator

Fault conditions are calculated on a per-PWM generator basis. Each PWM generator configures the necessary conditions to indicate a fault condition exists. This method allows the development of applications with dependent and independent control.

Four fault input pins (`MnFAULTn`) are available. These inputs may be used with circuits that generate an active High or active Low signal to indicate an error condition. A `MnFAULTn` pins may be individually programmed for the appropriate logic sense using the **PWMnFLTSEN** register.

The PWM generator's mode control, including fault condition handling, is provided in the **PWMnCTL** register. This register determines whether the input or a combination of `MnFAULTn` input signals and/or digital comparator triggers (as configured by the **PWMnFLTSRC0** and **PWMnFLTSRC1** registers) is used to generate a fault condition. The **PWMnCTL** register also selects whether the fault condition is maintained as long as the external condition lasts or if it is latched until the fault condition until cleared by software. Finally, this register also enables a counter that may be used to extend the period of a fault condition for external events to assure that the duration is a minimum length. The minimum fault period count is specified in the **PWMnMINFLTPER** register.

**Note:** When using an ADC digital comparator as a fault source, the `LATCH` and `MINFLTPER` bits in the **PWMnCTL** register should be set to 1 to ensure trigger assertions are captured.

Status regarding the specific fault cause is provided in the **PWMnFLTSTAT0** and **PWMnFLTSTAT1** registers. Note that the fault status registers, **PWMnFLTSTAT0** and **PWMnFLTSTAT1**, reflect the status of all fault sources, regardless of what fault sources are enabled for that particular generator.

PWM generator fault conditions may be promoted to a controller interrupt using the **PWMINTEN** register.

### 25.3.9 Output Control Block

The output control block takes care of the final conditioning of the `pwmA'` and `pwmB'` signals before they go to the pins as the `MnPWMn` signals. Via a single register, the **PWM Output Enable (PWENABLE)** register, the set of PWM signals that are actually enabled to the pins can be modified. This function can be used, for example, to perform commutation of a brushless DC motor with a single register write (and without modifying the individual PWM generators, which are modified by the feedback control loop). In addition, the updating of the bits in the **PWMENABLE** register can be configured to be immediate or locally or globally synchronized to the next synchronous update using the **PWM Enable Update (PWMENUUPD)** register.

During fault conditions, the PWM output signals, `MnPWMn`, usually must be driven to safe values so that external equipment may be safely controlled. The **PWMFAULT** register specifies whether during a fault condition, the generated signal continues to be passed driven or to an encoding specified in the **PWMFAULTVAL** register.

A final inversion can be applied to any of the `MnPWMn` signals, making them active Low instead of the default active High using the **PWM Output Inversion (PWMINVERT)**. The inversion is applied even if a value has been enabled in the **PWMFAULT** register and specified in the **PWMFAULTVAL** register. In other words, if a bit is set in the **PWMFAULT**, **PWMFAULTVAL**, and **PWMINVERT** registers, the output on the `MnPWMn` signal is 0, not 1 as specified in the **PWMFAULTVAL** register.

## 25.4 Initialization and Configuration

The following example shows how to initialize PWM Generator 0 with a 25-kHz frequency, a 25% duty cycle on the `MnPWM0` pin, and a 75% duty cycle on the `MnPWM1` pin. This example assumes the system clock is 20 MHz.

1. Enable the PWM clock by setting its corresponding bit in the **RCGCPWM** register in the System Control module (see page 395).
2. Enable the clock to the appropriate GPIO module via the **RCGCGPIO** register in the System Control module (see page 380).
3. In the GPIO module, enable the appropriate pins for their alternate function using the **GPIOAFSEL** register. To determine which GPIOs to configure, see Table 28-4 on page 1680.
4. Configure the `PMCn` fields in the **GPIOPCTL** register to assign the PWM signals to the appropriate pins (see page 779 and Table 28-5 on page 1693).
5. Configure the **PWM Clock Configuration (PWMCC)** register to use the PWM divide (`USEPWMDIV`) and set the divider (`PWMDIV`) to divide by 2 (`0x0`).
6. Configure the PWM generator for countdown mode with immediate updates to the parameters.
  - Write the **PWM0CTL** register with a value of `0x0000.0000`.
  - Write the **PWM0GENA** register with a value of `0x0000.008C`.
  - Write the **PWM0GENB** register with a value of `0x0000.080C`.
7. Set the period. For a 25-KHz frequency, the period =  $1/25,000$ , or 40 microseconds. The PWM clock source is 10 MHz; the system clock divided by 2. Thus there are 400 clock ticks per period. Use this value to set the **PWM0LOAD** register. In Count-Down mode, set the `LOAD` field in the **PWM0LOAD** register to the requested period minus one.

- Write the **PWM0LOAD** register with a value of 0x0000.018F.
8. Set the pulse width of the M<sub>n</sub>PWM0 pin for a 25% duty cycle.
    - Write the **PWM0CMPA** register with a value of 0x0000.012B.
  9. Set the pulse width of the M<sub>n</sub>PWM1 pin for a 75% duty cycle.
    - Write the **PWM0CMPB** register with a value of 0x0000.0063.
  10. Start the timers in PWM generator 0.
    - Write the **PWM0CTL** register with a value of 0x0000.0001.
  11. Enable PWM outputs.
    - Write the **PWMENABLE** register with a value of 0x0000.0003.

## 25.5 Register Map

Table 25-2 on page 1553 lists the PWM registers. The offset listed is a hexadecimal increment to the register's address, relative to the PWM module's base address:

- PWM0: 0x4002.8000

Note that the PWM module clock must be enabled before the registers can be programmed. There must be a delay of 3 system clocks after the PWM module clock is enabled before any PWM module registers are accessed.

**Table 25-2. PWM Register Map**

| Offset | Name        | Type | Reset       | Description                       | See page |
|--------|-------------|------|-------------|-----------------------------------|----------|
| 0x000  | PWMCTL      | RW   | 0x0000.0000 | PWM Master Control                | 1557     |
| 0x004  | PWMSYNC     | RW   | 0x0000.0000 | PWM Time Base Sync                | 1559     |
| 0x008  | PWMENABLE   | RW   | 0x0000.0000 | PWM Output Enable                 | 1560     |
| 0x00C  | PWMINVERT   | RW   | 0x0000.0000 | PWM Output Inversion              | 1562     |

## 25.6 Register Descriptions

The remainder of this section lists and describes the PWM registers, in numerical order by address offset.

**Register 1: PWM Master Control (PWMCTL), offset 0x000**

This register provides master control over the PWM generation blocks.

**PWM Master Control (PWMCTL)**

PWM0 base: 0x4002.8000

Offset 0x000

Type RW, reset 0x0000.0000

|       |          |    |    |    |    |    |    |    |    |    |    |    |             |             |             |             |    |

| 0         | GLOBALSYNC0 | RW   | 0     | Update PWM Generator 0<br><br>Value Description<br>0 No effect.<br>1 Any queued update to a load or comparator register in PWM generator 0 is applied the next time the corresponding counter becomes zero.<br><br>This bit automatically clears when the updates have completed; it cannot be cleared by software. |

## Register 2: PWM Time Base Sync (PWMSYNC), offset 0x004

This register provides a method to perform synchronization of the counters in the PWM generation blocks. Setting a bit in this register causes the specified counter to reset back to 0; setting multiple bits resets multiple counters simultaneously. The bits auto-clear after the reset has occurred; reading them back as zero indicates that the synchronization has completed.

### PWM Time Base Sync (PWMSYNC)

PWM0 base: 0x4002.8000

Offset 0x004

Type RW, reset 0x0000.0000

### Register 3: PWM Output Enable (PWMENABLE), offset 0x008

This register provides a master control of which generated pwmA' and pwmB' signals are output to the  $M_nPWM_n$  pins. By disabling a PWM output, the generation process can continue (for example, when the time bases are synchronized) without driving PWM signals to the pins. When bits in this register are set, the corresponding pwmA' or pwmB' signal is passed through to the output stage. When bits are clear, the pwmA' or pwmB' signal is replaced by a zero value which is also passed to the output stage. The **PWMINVERT** register controls the output stage, so if the corresponding bit is set in that register, the value seen on the  $M_nPWM_n$  signal is inverted from what is configured by the bits in this register. Updates to the bits in this register can be immediate or locally or globally synchronized to the next synchronous update as controlled by the  $ENUPD_n$  fields in the **PWMENUPD** register.

### Register 4: PWM Output Inversion (PWMINVERT), offset 0x00C

This register provides a master control of the polarity of the  $M_nPWM_n$  signals on the device pins. The  $pwmA'$  and  $pwmB'$  signals generated by the PWM generator are active High; but can be made active Low via this register. Disabled PWM channels are also passed through the output inverter (if so configured) so that inactive signals can be High. In addition, if the **PWMFAULT** register enables a specific value to be placed on the  $M_nPWM_n$  signals during a fault condition, that value is inverted if the corresponding bit in this register is set.

### Register 5: PWM Output Fault (PWMFAULT), offset 0x010

This register controls the behavior of the  $M_nP_{WMn}$  outputs in the presence of fault conditions. Both the fault inputs ( $M_nFAULT_n$  pins and digital comparator outputs) and debug events are considered fault conditions. On a fault condition, each  $pwmA'$  or  $pwmB'$  signal can be passed through unmodified or driven to the value specified by the corresponding bit in the **PWMFAULTVAL** register. For outputs that are configured for pass-through, the debug event handling on the corresponding PWM generator also determines if the  $pwmA'$  or  $pwmB'$  signal continues to be generated.

Fault condition control occurs before the output inverter, so PWM signals driven to a specified value on fault are inverted if the channel is configured for inversion (therefore, the pin is driven to the logical complement of the specified value on a fault condition).

### Register 6: PWM Interrupt Enable (PWMINTEN), offset 0x014

This register controls the global interrupt generation capabilities of the PWM module. The events that can cause an interrupt are the fault input and the individual interrupts from the PWM generators.

**Note:** The "n" in the INTFAULT<sub>n</sub> and INTPWM<sub>n</sub> bits in this register correspond to the PWM generators, not to the FAULT<sub>n</sub> signals.

### Register 7: PWM Raw Interrupt Status (PWMRIS), offset 0x018

This register provides the current set of interrupt sources that are asserted, regardless of whether they are enabled to cause an interrupt to be asserted to the interrupt controller. The fault interrupt is asserted based on the fault condition source that is specified by the **PWMnCTL**, **PWMnFLTSRC0** and **PWMnFLTSRC1** registers. The fault interrupt is latched on detection and must be cleared through the **PWM Interrupt Status and Clear (PWMISC)** register. The actual value of the  $M_nFAULTn$  signals can be observed using the **PWMSTATUS** register.

The PWM generator interrupts simply reflect the status of the PWM generators and are cleared via the interrupt status register in the PWM generator blocks. If a bit is set, the event is active; if a bit is clear the event is not active.

| 0         | INTPWM0 | RO   | 0     | PWM0 Interrupt Asserted |

Value Description

0 The PWM generator 0 block interrupt has not been asserted.

1 The PWM generator 0 block interrupt is asserted.

The **PWM0RIS** register shows the source of this interrupt. This bit is cleared by writing a 1 to the corresponding bit in the **PWM0ISC** register.

## Register 8: PWM Interrupt Status and Clear (PWMISC), offset 0x01C

This register provides a summary of the interrupt status of the individual PWM generator blocks. If a fault interrupt is set, the corresponding  $M_nFAULT_n$  input has caused an interrupt. For the fault interrupt, a write of 1 to that bit position clears the latched interrupt status. If an block interrupt bit is set, the corresponding generator block is asserting an interrupt. The individual interrupt status registers, **PWMnISC**, in each block must be consulted to determine the reason for the interrupt and used to clear the interrupt.

### Register 10: PWM Fault Condition Value (PWMFAULTVAL), offset 0x024

This register specifies the output value driven on the  $M_nPWM_n$  signals during a fault condition if enabled by the corresponding bit in the **PWMFAULT** register. Note that if the corresponding bit in the **PWMINVERT** register is set, the output value is driven to the logical NOT of the bit value in this register.

#### PWM Fault Condition Value (PWMFAULTVAL)

### Register 11: PWM Enable Update (PWMENUPD), offset 0x028

This register specifies when updates to the  $PWM_nEN$  bit in the **PWMENABLE** register are performed. The  $PWM_nEN$  bit enables the pwmA' or pwmB' output to be passed to the microcontroller's pin. Updates can be immediate or locally or globally synchronized to the next synchronous update.

**Register 12: PWM0 Control (PWM0CTL), offset 0x040**

**Register 13: PWM1 Control (PWM1CTL), offset 0x080**

**Register 14: PWM2 Control (PWM2CTL), offset 0x0C0**

**Register 15: PWM3 Control (PWM3CTL), offset 0x100**

These registers configure the PWM signal generation blocks (PWM0CTL controls the PWM generator 0 block, and so on). The Register Update mode, Debug mode, Counting mode, and Block Enable mode are all controlled via these registers. The blocks produce the PWM signals, which can be either two independent PWM signals (from the same counter), or a paired set of PWM signals with dead-band delays added.

The PWM0 block produces the  $M_n$ PWM0 and  $M_n$ PWM1 outputs, the PWM1 block produces the  $M_n$ PWM2 and  $M_n$ PWM3 outputs, the PWM2 block produces the  $M_n$ PWM4 and  $M_n$ PWM5 outputs, and the PWM3 block produces the  $M_n$ PWM6 and  $M_n$ PWM7 outputs.

The timer ignores the state of the fault condition while counting.</p> <p>The minimum fault delay is in effect only when the MINFLTPER bit is set. If a detected fault is in the process of being extended when the MINFLTPER bit is cleared, the fault condition extension is aborted.</p> <p>The delay time is specified by the <b>PWMnMINFLTPER</b> register MFP field value. The effect of this is to pulse stretch the fault condition input.</p> <p>The delay value is defined by the PWM clock period. Because the fault input is not synchronized to the PWM clock, the period of the time is <math>PWMClock * (MFP \text{ value} + 1)</math> or <math>PWMClock * (MFP \text{ value} + 2)</math>.</p> <p>The delay function makes sense only if the fault source is unlatched. A latched fault source makes the fault condition appear asserted until cleared by software and negates the utility of the extend feature. It applies to all fault condition sources as specified in the FLTSRC field.</p> <p>Value Description</p> <p>0 The FAULT input deassertion is unaffected.</p> <p>1 The <b>PWMnMINFLTPER</b> one-shot counter is active and extends the period of the fault condition to a minimum period.</p> <p><b>Note:</b> When using an ADC digital comparator as a fault source, the LATCH and MINFLTPER bits in the <b>PWMnCTL</b> register should be set to 1 to ensure trigger assertions are captured.</p> |
| 16        | FLTSRC    | RW   | 0     | <p>Fault Condition Source</p> <p>Value Description</p> <p>0 The Fault condition is determined by the Fault0 input.</p> <p>1 The Fault condition is determined by the configuration of the <b>PWMnFLTSRC0</b> and <b>PWMnFLTSRC1</b> registers.</p>   |

|           |        |      |       | <b>Note:</b> Disabling the PWM by clearing the <code>ENABLE</code> bit does not clear the <code>COUNT</code> field of the <code>PWMnCOUNT</code> register. Before re-enabling the PWM ( <code>ENABLE = 0x1</code> ), the <code>COUNT</code> field should be cleared by resetting the PWM registers through the <code>SRPWM</code> register in the System Control Module. |
|           |        |      |       | Value Description<br>0 The entire PWM generation block is disabled and not clocked.<br>1 The PWM generation block is enabled and produces PWM signals.   |

**Register 16: PWM0 Interrupt and Trigger Enable (PWM0INTEN), offset 0x044**

**Register 17: PWM1 Interrupt and Trigger Enable (PWM1INTEN), offset 0x084**

**Register 18: PWM2 Interrupt and Trigger Enable (PWM2INTEN), offset 0x0C4**

**Register 19: PWM3 Interrupt and Trigger Enable (PWM3INTEN), offset 0x104**

These registers control the interrupt and ADC trigger generation capabilities of the PWM generators (**PWM0INTEN** controls the PWM generator 0 block, and so on). The events that can cause an interrupt, or an ADC trigger are:

- The counter being equal to the load register
- The counter being equal to zero
- The counter being equal to the **PWMnCMPA** register while counting up
- The counter being equal to the **PWMnCMPA** register while counting down
- The counter being equal to the **PWMnCMPB** register while counting up
- The counter being equal to the **PWMnCMPB** register while counting down

Any combination of these events can generate either an interrupt or an ADC trigger, though no determination can be made as to the actual event that caused an ADC trigger if more than one is specified. The **PWMnRIS** register provides information about which events have caused raw interrupts.

**Register 20: PWM0 Raw Interrupt Status (PWM0RIS), offset 0x048**

**Register 21: PWM1 Raw Interrupt Status (PWM1RIS), offset 0x088**

**Register 22: PWM2 Raw Interrupt Status (PWM2RIS), offset 0x0C8**

**Register 23: PWM3 Raw Interrupt Status (PWM3RIS), offset 0x108**

These registers provide the current set of interrupt sources that are asserted, regardless of whether they cause an interrupt to be asserted to the controller (**PWM0RIS** controls the PWM generator 0 block, and so on). If a bit is set, the event has occurred; if a bit is clear, the event has not occurred. Bits in this register are cleared by writing a 1 to the corresponding bit in the **PWMnISC** register.

**Register 24: PWM0 Interrupt Status and Clear (PWM0ISC), offset 0x04C**

**Register 25: PWM1 Interrupt Status and Clear (PWM1ISC), offset 0x08C**

**Register 26: PWM2 Interrupt Status and Clear (PWM2ISC), offset 0x0CC**

**Register 27: PWM3 Interrupt Status and Clear (PWM3ISC), offset 0x10C**

These registers provide the current set of interrupt sources that are asserted to the interrupt controller (**PWM0ISC** controls the PWM generator 0 block, and so on). A bit is set if the event has occurred and is enabled in the **PWMnINTEN** register; if a bit is clear, the event has not occurred or is not enabled. These are RW1C registers; writing a 1 to a bit position clears the corresponding interrupt reason.

**Note:** The interrupt status can only be cleared one PWM Clock cycle after the interrupt occurs. The larger the PWM Clock Divider (**PWMDIV**) value in **PWMCC** register, the longer the system delay is to clear the interrupt.

**Register 28: PWM0 Load (PWM0LOAD), offset 0x050**

**Register 29: PWM1 Load (PWM1LOAD), offset 0x090**

**Register 30: PWM2 Load (PWM2LOAD), offset 0x0D0**

**Register 31: PWM3 Load (PWM3LOAD), offset 0x110**

These registers contain the load value for the PWM counter (**PWM0LOAD** controls the PWM generator 0 block, and so on). Based on the counter mode configured by the **MODE** bit in the **PWMnCTL** register, this value is either loaded into the counter after it reaches zero or is the limit of up-counting after which the counter decrements back to zero. When this value matches the counter, a pulse is output which can be configured to drive the generation of the **pwmA** and/or **pwmB** signal (via the **PWMnGENA/PWMnGENB** register) or drive an interruptor ADC trigger (via the **PWMnINTEN** register).

If the Load Value Update mode is locally synchronized (based on the **LOADUPD** field encoding in the **PWMnCTL** register), the 16-bit **LOAD** value is used the next time the counter reaches zero. If the update mode is globally synchronized, it is used the next time the counter reaches zero after a synchronous update has been requested through the **PWM Master Control (PWMCTL)** register (see page 1557). If this register is re-written before the actual update occurs, the previous value is never used and is lost.

**Register 32: PWM0 Counter (PWM0COUNT), offset 0x054****Register 33: PWM1 Counter (PWM1COUNT), offset 0x094****Register 34: PWM2 Counter (PWM2COUNT), offset 0x0D4****Register 35: PWM3 Counter (PWM3COUNT), offset 0x114**

These registers contain the current value of the PWM counter (**PWM0COUNT** is the value of the PWM generator 0 block, and so on). When this value matches zero or the value in the **PWMnLOAD**, **PWMnCMPA**, or **PWMnCMPB** registers, a pulse is output which can be configured to drive the generation of a PWM signal or drive an interrupt or ADC trigger.

**Note:** Disabling the PWM by clearing the **ENABLE** bit does not clear the **COUNT** field of the **PWMnCOUNT** register. Before re-enabling the PWM (**ENABLE** = 0x1), the **COUNT** field should be cleared by resetting the PWM registers through the **SRPWM** register in the System Control Module.

## PWMn Counter (PWMnCOUNT)

| Bit/Field | Name     | Type | Reset  | Description   |
|-----------|----------|------|--------|---|
| 31:16     | reserved | RO   | 0x0000 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 15:0      | COUNT    | RO   | 0x0000 | Counter Value<br>The current value of the counter.  |

**Register 36: PWM0 Compare A (PWM0CMPA), offset 0x058**

**Register 37: PWM1 Compare A (PWM1CMPA), offset 0x098**

**Register 38: PWM2 Compare A (PWM2CMPA), offset 0x0D8**

**Register 39: PWM3 Compare A (PWM3CMPA), offset 0x118**

These registers contain a value to be compared against the counter (**PWM0CMPA** controls the PWM generator 0 block, and so on). When this value matches the counter, a pulse is output which can be configured to drive the generation of the pwmA and pwmB signals (via the **PWMnGENA** and **PWMnGENB** registers) or drive an interrupt or ADC trigger (via the **PWMnINTEN** register). If the value of this register is greater than the **PWMnLOAD** register (see page 1594), then no pulse is ever output.

If the comparator A update mode is locally synchronized (based on the **COMPAUPD** bit in the **PWMnCTL** register), the 16-bit **COMPA** value is used the next time the counter reaches zero. If the update mode is globally synchronized, it is used the next time the counter reaches zero after a synchronous update has been requested through the **PWM Master Control (PWMCTL)** register (see page 1557). If this register is rewritten before the actual update occurs, the previous value is never used and is lost.

PWMn Compare A (PWMnCMPA)

PWM0 base: 0x4002.8000  
 Offset 0x058  
 Type RW, reset 0x0000.0000

| Bit/Field | Name     | Type | Reset | Description   |
|-----------|----------|------|-------|---|
| 31:16     | reserved | RO   | 0x00  | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |

**Register 44: PWM0 Generator A Control (PWM0GENA), offset 0x060**

**Register 45: PWM1 Generator A Control (PWM1GENA), offset 0x0A0**

**Register 46: PWM2 Generator A Control (PWM2GENA), offset 0x0E0**

**Register 47: PWM3 Generator A Control (PWM3GENA), offset 0x120**

These registers control the generation of the pwmA signal based on the load and zero output pulses from the counter, as well as the compare A and compare B pulses from the comparators (**PWM0GENA** controls the PWM generator 0 block, and so on). When the counter is running in Count-Down mode, only four of these events occur; when running in Count-Up/Down mode, all six occur. These events provide great flexibility in the positioning and duty cycle of the resulting PWM signal.

The **PWM0GENA** register controls generation of the pwm0A signal; **PWM1GENA**, the pwm1A signal; **PWM2GENA**, the pwm2A signal; and **PWM3GENA**, the pwm3A signal.

If a zero or load event coincides with a compare A or compare B event, the zero or load action is taken and the compare A or compare B action is ignored. If a compare A event coincides with a compare B event, the compare A action is taken and the compare B action is ignored.

If the Generator A update mode is immediate (based on the **GENAUPD** field encoding in the **PWMnCTL** register), the **ACTCMPBD**, **ACTCMPBU**, **ACTCMPAD**, **ACTCMPAU**, **ACTLOAD**, and **ACTZERO** values are used immediately. If the update mode is locally synchronized, these values are used the next time the counter reaches zero. If the update mode is globally synchronized, these values are used the next time the counter reaches zero after a synchronous update has been requested through the **PWM Master Control (PWMCTL)** register (see page 1557). If this register is rewritten before the actual update occurs, the previous value is never used and is lost.

PWMn Generator A Control (PWMnGENA)

PWM0 base: 0x4002.8000  
Offset 0x060  
Type RW, reset 0x0000.0000

**Register 48: PWM0 Generator B Control (PWM0GENB), offset 0x064****Register 49: PWM1 Generator B Control (PWM1GENB), offset 0x0A4****Register 50: PWM2 Generator B Control (PWM2GENB), offset 0x0E4****Register 51: PWM3 Generator B Control (PWM3GENB), offset 0x124**

These registers control the generation of the pwmB signal based on the load and zero output pulses from the counter, as well as the compare A and compare B pulses from the comparators (**PWM0GENB** controls the PWM generator 0 block, and so on). When the counter is running in Count-Down mode, only four of these events occur; when running in Count-Up/Down mode, all six occur. These events provide great flexibility in the positioning and duty cycle of the resulting PWM signal.

The **PWM0GENB** register controls generation of the pwm0B signal; **PWM1GENB**, the pwm1B signal; **PWM2GENB**, the pwm2B signal; and **PWM3GENB**, the pwm3B signal.

If a zero or load event coincides with a compare A or compare B event, the zero or load action is taken and the compare A or compare B action is ignored. If a compare A event coincides with a compare B event, the compare B action is taken and the compare A action is ignored.

If the Generator B update mode is immediate (based on the **GENBUPD** field encoding in the **PWMnCTL** register), the **ACTCMPBD**, **ACTCMPBU**, **ACTCMPAD**, **ACTCMPAU**, **ACTLOAD**, and **ACTZERO** values are used immediately. If the update mode is locally synchronized, these values are used the next time the counter reaches zero. If the update mode is globally synchronized, these values are used the next time the counter reaches zero after a synchronous update has been requested through the **PWM Master Control (PWMCTL)** register (see page 1557). If this register is rewritten before the actual update occurs, the previous value is never used and is lost.

**Register 52: PWM0 Dead-Band Control (PWM0DBCTL), offset 0x068**

**Register 53: PWM1 Dead-Band Control (PWM1DBCTL), offset 0x0A8**

**Register 54: PWM2 Dead-Band Control (PWM2DBCTL), offset 0x0E8**

**Register 55: PWM3 Dead-Band Control (PWM3DBCTL), offset 0x128**

The **PWMnDBCTL** register controls the dead-band generator, which produces the  $M_nP_{WMn}$  signals based on the *pwmA* and *pwmB* signals. When disabled, the *pwmA* signal passes through to the *pwmA'* signal and the *pwmB* signal passes through to the *pwmB'* signal. When dead-band control is enabled, the *pwmB* signal is ignored, the *pwmA'* signal is generated by delaying the rising edge(s) of the *pwmA* signal by the value in the **PWMnDBRISE** register (see page 1605), and the *pwmB'* signal is generated by inverting the *pwmA* signal and delaying the falling edge(s) of the *pwmA* signal by the value in the **PWMnDBFALL** register (see page 1606). The Output Control block outputs the *pwm0A'* signal on the  $M_nP_{WM0}$  signal and the *pwm0B'* signal on the  $M_nP_{WM1}$  signal. In a similar manner,  $M_nP_{WM2}$  and  $M_nP_{WM3}$  are produced from the *pwm1A'* and *pwm1B'* signals,  $M_nP_{WM4}$  and  $M_nP_{WM5}$  are produced from the *pwm2A'* and *pwm2B'* signals, and  $M_nP_{WM6}$  and  $M_nP_{WM7}$  are produced from the *pwm3A'* and *pwm3B'* signals.

If the Dead-Band Control mode is immediate (based on the **DBCTLUPD** field encoding in the **PWMnCTL** register), the **ENABLE** bit value is used immediately. If the update mode is locally synchronized, this value is used the next time the counter reaches zero. If the update mode is globally synchronized, this value is used the next time the counter reaches zero after a synchronous update has been requested through the **PWM Master Control (PWMCTL)** register (see page 1557). If this register is rewritten before the actual update occurs, the previous value is never used and is lost.

|-----------|----------|------|------------|---|
| 31:1      | reserved | RO   | 0x0000.000 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 0         | ENABLE   | RW   | 0          | Dead-Band Generator Enable  |
|           |          |      |            | Value Description   |
|           |          |      | 0          | The <i>pwmA</i> and <i>pwmB</i> signals pass through to the <i>pwmA'</i> and <i>pwmB'</i> signals unmodified.   |
|           |          |      | 1          | The dead-band generator modifies the <i>pwmA</i> signal by inserting dead bands into the <i>pwmA'</i> and <i>pwmB'</i> signals.   |

**Register 56: PWM0 Dead-Band Rising-Edge Delay (PWM0DBRISE), offset 0x06C**

**Register 57: PWM1 Dead-Band Rising-Edge Delay (PWM1DBRISE), offset 0x0AC**

**Register 58: PWM2 Dead-Band Rising-Edge Delay (PWM2DBRISE), offset 0x0EC**

**Register 59: PWM3 Dead-Band Rising-Edge Delay (PWM3DBRISE), offset 0x12C**

The **PWMnDBRISE** register contains the number of clock cycles to delay the rising edge of the pwmA signal when generating the pwmA' signal. If the dead-band generator is disabled through the **PWMnDBCTL** register, this register is ignored. If the value of this register is larger than the width of a High pulse on the pwmA signal, the rising-edge delay consumes the entire High time of the signal, resulting in no High time on the output. Care must be taken to ensure that the pwmA High time always exceeds the rising-edge delay.

If the Dead-Band Rising-Edge Delay mode is immediate (based on the **DBRISEUPD** field encoding in the **PWMnCTL** register), the 12-bit **RISEDELAY** value is used immediately. If the update mode is locally synchronized, this value is used the next time the counter reaches zero. If the update mode is globally synchronized, this value is used the next time the counter reaches zero after a synchronous update has been requested through the **PWM Master Control (PWMCTL)** register (see page 1557). If this register is rewritten before the actual update occurs, the previous value is never used and is lost.

| Bit/Field | Name      | Type | Reset    | Description   |
|-----------|-----------|------|----------|---|
| 31:12     | reserved  | RO   | 0x0000.0 | Software should not rely on the value of a reserved bit. To provide compatibility with future products, the value of a reserved bit should be preserved across a read-modify-write operation. |
| 11:0      | RISEDELAY | RW   | 0x000    | Dead-Band Rise Delay<br>The number of clock cycles to delay the rising edge of pwmA' after the rising edge of pwmA.   |

**Register 60: PWM0 Dead-Band Falling-Edge-Delay (PWM0DBFALL), offset 0x070**

**Register 61: PWM1 Dead-Band Falling-Edge-Delay (PWM1DBFALL), offset 0x0B0**

**Register 62: PWM2 Dead-Band Falling-Edge-Delay (PWM2DBFALL), offset 0x0F0**

**Register 63: PWM3 Dead-Band Falling-Edge-Delay (PWM3DBFALL), offset 0x130**

The **PWMnDBFALL** register contains the number of clock cycles to delay the rising edge of the pwmB' signal from the falling edge of the pwmA signal. If the dead-band generator is disabled through the **PWMnDBCTL** register, this register is ignored. If the value of this register is larger than the width of a Low pulse on the pwmA signal, the falling-edge delay consumes the entire Low time of the signal, resulting in no Low time on the output. Care must be taken to ensure that the pwmA Low time always exceeds the falling-edge delay.

If the Dead-Band Falling-Edge-Delay mode is immediate (based on the **DBFALLUP** field encoding in the **PWMnCTL** register), the 12-bit **FALLDELAY** value is used immediately. If the update mode is locally synchronized, this value is used the next time the counter reaches zero. If the update mode is globally synchronized, this value is used the next time the counter reaches zero after a synchronous update has been requested through the **PWM Master Control (PWMCTL)** register (see page 1557). If this register is rewritten before the actual update occurs, the previous value is never used and is lost.

**PWMn Dead-Band Falling-Edge-Delay (PWMnDBFALL)**

**Register 72: PWM0 Minimum Fault Period (PWM0MINFLTPER), offset 0x07C**

**Register 73: PWM1 Minimum Fault Period (PWM1MINFLTPER), offset 0x0BC**

**Register 74: PWM2 Minimum Fault Period (PWM2MINFLTPER), offset 0x0FC**

**Register 75: PWM3 Minimum Fault Period (PWM3MINFLTPER), offset 0x13C**

If the `MINFLTPER` bit in the `PWMnCTL` register is set, this register specifies the 16-bit time-extension value to be used in extending the fault condition. The value is loaded into a 16-bit down counter, and the counter value is used to extend the fault condition. The fault condition is released in the clock immediately after the counter value reaches 0. The fault condition is asynchronous to the PWM clock; and the delay value is the product of the PWM clock period and the (MFP field value + 1) or (MFP field value + 2) depending on when the fault condition asserts with respect to the PWM clock. The counter decrements at the PWM clock rate, without pause or condition.

**Register 80: PWM0 Fault Status 0 (PWM0FLTSTAT0), offset 0x804**

**Register 81: PWM1 Fault Status 0 (PWM1FLTSTAT0), offset 0x884**

**Register 82: PWM2 Fault Status 0 (PWM2FLTSTAT0), offset 0x904**

**Register 83: PWM3 Fault Status 0 (PWM3FLTSTAT0), offset 0x984**

Along with the **PWMnFLTSTAT1** register, this register provides status regarding the fault condition inputs.

If the **LATCH** bit in the **PWMnCTL** register is clear, the contents of the **PWMnFLTSTAT0** register are read-only (RO) and provide the current state of the **MnFAULTn** inputs.

If the **LATCH** bit in the **PWMnCTL** register is set, the contents of the **PWMnFLTSTAT0** register are read / write 1 to clear (RW1C) and provide a latched version of the **MnFAULTn** inputs. In this mode, the register bits are cleared by writing a 1 to a set bit. The **MnFAULTn** inputs are recorded after their sense is adjusted in the generator.

The contents of this register can only be written if the fault source extensions are enabled (the **FLTSRC** bit in the **PWMnCTL** register is set).

**Note:** The fault status registers, **PWMnFLTSTAT0** and **PWMnFLTSTAT1**, reflect the status of all fault sources, regardless of what fault sources are enabled for that particular generator.

**Register 84: PWM0 Fault Status 1 (PWM0FLTSTAT1), offset 0x808**

**Register 85: PWM1 Fault Status 1 (PWM1FLTSTAT1), offset 0x888**

**Register 86: PWM2 Fault Status 1 (PWM2FLTSTAT1), offset 0x908**

**Register 87: PWM3 Fault Status 1 (PWM3FLTSTAT1), offset 0x988**

Along with the **PWMnFLTSTAT0** register, this register provides status regarding the fault condition inputs.

If the **LATCH** bit in the **PWMnCTL** register is clear, the contents of the **PWMnFLTSTAT1** register are read-only (RO) and provide the current state of the digital comparator triggers.

If the **LATCH** bit in the **PWMnCTL** register is set, the contents of the **PWMnFLTSTAT1** register are read / write 1 to clear (RW1C) and provide a latched version of the digital comparator triggers. In this mode, the register bits are cleared by writing a 1 to a set bit. The contents of this register can only be written if the fault source extensions are enabled (the **FLTSRC** bit in the **PWMnCTL** register is set).

**Note:** The fault status registers, **PWMnFLTSTAT0** and **PWMnFLTSTAT1**, reflect the status of all fault sources, regardless of what fault sources are enabled for that particular generator.

## 26 Quadrature Encoder Interface (QEI)

A quadrature encoder, also known as a 2-channel incremental encoder, converts linear displacement into a pulse signal. By monitoring both the number of pulses and the relative phase of the two signals, you can track the position, direction of rotation, and speed. In addition, a third channel, or index signal, can be used to reset the position counter.

The TM4C129CNCZAD quadrature encoder interface (QEI) module interprets the code produced by a quadrature encoder wheel to integrate position over time and determine direction of rotation. In addition, it can capture a running estimate of the velocity of the encoder wheel.

The TM4C129CNCZAD microcontroller includes one QEI module with the following features:

- Position integrator that tracks the encoder position
- Programmable noise filter on the inputs
- Velocity capture using built-in timer
- The input frequency of the QEI inputs may be as high as 1/4 of the processor frequency (for example, 12.5 MHz for a 50-MHz system)
- Interrupt generation on:
  - Index pulse
  - Velocity-timer expiration
  - Direction change
  - Quadrature error detection

### 26.1 Block Diagram

Figure 26-1 on page 1623 provides an internal block diagram of a TM4C129CNCZAD QEI module. The PhA and PhB inputs shown in this diagram are the internal signals that enter the Quadrature Encoder after the external signals,  $PhAn$  and  $PhBn$ , have passed through inversion and swapping logic shown in Figure 26-2 on page 1624. The QEI module has the option of inverting and/or swapping the incoming signals.

**Note:** Any references in this chapter to PhA and PhB refer to the internal PhA and PhB inputs that enter the Quadrature Encoder after the external signals,  $PhAn$  and  $PhBn$ , have passed through inversion and swapping logic that is enabled through the **QEI Control (QEICTL)** register.

Figure 26-1. QEI Block Diagram

Figure 26-2 on page 1624 shows the logic that is provided to allow the `PhAn` and `PhBn` signals to be inverted and/or swapped.

Figure 26-2. QEI Input Signal Logic

## 26.2 Signal Description

The following table lists the external signals of the QEI module and describes the function of each. The QEI signals are alternate functions for some GPIO signals and default to be GPIO signals at reset. The column in the table below titled "Pin Mux/Pin Assignment" lists the possible GPIO pin placements for these QEI signals. The `AFSEL` bit in the **GPIO Alternate Function Select (GPIOAFSEL)** register (page 762) should be set to choose the QEI function. The number in parentheses is the encoding that must be programmed into the `PMCn` field in the **GPIO Port Control (GPIOCTL)** register (page 779) to assign the QEI signal to the specified GPIO port pin. For more information on configuring GPIOs, see "General-Purpose Input/Outputs (GPIOs)" on page 731.

Table 26-1. QEI Signals (212BGA)

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type | Description           |

## 26.3 Functional Description

The QEI module interprets the two-bit gray code produced by a quadrature encoder wheel to integrate position over time and determine direction of rotation. In addition, it can capture a running estimate of the velocity of the encoder wheel.

The position integrator and velocity capture can be independently enabled, though the position integrator must be enabled before the velocity capture can be enabled. The two phase signals,

$Ph_{An}$  and  $Ph_{Bn}$ , can be swapped before being interpreted by the QEI module to change the meaning of forward and backward and to correct for miswiring of the system. Alternatively, the phase signals can be interpreted as a clock and direction signal as output by some encoders.

The QEI module input signals have a digital noise filter on them that can be enabled to prevent spurious operation. The noise filter requires that the inputs be stable for a specified number of consecutive clock cycles before updating the edge detector. The filter is enabled by the `FILTEN` bit in the **QEI Control (QEICTL)** register. The frequency of the input update is programmable using the `FILTCNT` bit field in the **QEICTL** register.

The QEI module supports two modes of signal operation: quadrature phase mode and clock/direction mode. In quadrature phase mode, the encoder produces two clocks that are 90 degrees out of phase; the edge relationship is used to determine the direction of rotation. In clock/direction mode, the encoder produces a clock signal to indicate steps and a direction signal to indicate the direction of rotation. This mode is determined by the `SIGMODE` bit of the **QEICTL** register (see page 1629).

When the QEI module is set to use the quadrature phase mode (`SIGMODE` bit is clear), the capture mode for the position integrator can be set to update the position counter on every edge of the  $Ph_A$  signal or to update on every edge of both  $Ph_A$  and  $Ph_B$ . Updating the position counter on every  $Ph_A$  and  $Ph_B$  edge provides more positional resolution at the cost of less range in the positional counter.

When edges on  $Ph_A$  lead edges on  $Ph_B$ , the position counter is incremented. When edges on  $Ph_B$  lead edges on  $Ph_A$ , the position counter is decremented. When a rising and falling edge pair is seen on one of the phases without any edges on the other, the direction of rotation has changed.

The positional counter is automatically reset on one of two conditions: sensing the index pulse or reaching the maximum position value. The reset mode is determined by the `RESMODE` bit of the **QEICTL** register.

When `RESMODE` is set, the positional counter is reset when the index pulse is sensed. This mode limits the positional counter to the values  $[0:N-1]$ , where  $N$  is the number of phase edges in a full revolution of the encoder wheel. The **QEI Maximum Position (QEIMAXPOS)** register must be programmed with  $N-1$  so that the reverse direction from position 0 can move the position counter to  $N-1$ . In this mode, the position register contains the absolute position of the encoder relative to the index (or home) position once an index pulse has been seen.

When `RESMODE` is clear, the positional counter is constrained to the range  $[0:M]$ , where  $M$  is the programmable maximum value. The index pulse is ignored by the positional counter in this mode.

Velocity capture uses a configurable timer and a count register. The timer counts the number of phase edges (using the same configuration as for the position integrator) in a given time period. The edge count from the previous time period is available to the controller via the **QEI Velocity (QEISPEED)** register, while the edge count for the current time period is being accumulated in the **QEI Velocity Counter (QEICOUNT)** register. As soon as the current time period is complete, the total number of edges counted in that time period is made available in the **QEISPEED** register (overwriting the previous value), the **QEICOUNT** register is cleared, and counting commences on a new time period. The number of edges counted in a given time period is directly proportional to the velocity of the encoder.

Figure 26-3 on page 1626 shows how the TM4C129CNCZAD quadrature encoder converts the phase input signals into clock pulses, the direction signal, and how the velocity predivider operates (in Divide by 4 mode).

**Figure 26-3. Quadrature Encoder and Velocity Predivider Operation**

The period of the timer is configurable by specifying the load value for the timer in the **QEI Timer Load (QEILOAD)** register. When the timer reaches zero, an interrupt can be triggered, and the hardware reloads the timer with the **QEILOAD** value and continues to count down. At lower encoder speeds, a longer timer period is required to be able to capture enough edges to have a meaningful result. At higher encoder speeds, both a shorter timer period and/or the velocity predivider can be used.

The following equation converts the velocity counter value into an rpm value:

$$\text{rpm} = (\text{clock} * (2 \wedge \text{VELDIV}) * \text{SPEED} * 60) \div (\text{LOAD} * \text{ppr} * \text{edges})$$

where:

clock is the controller clock rate

ppr is the number of pulses per revolution of the physical encoder

edges is 2 or 4, based on the capture mode set in the **QEICTL** register (2 for CAPMODE clear and 4 for CAPMODE set)

For example, consider a motor running at 600 rpm. A 2048 pulse per revolution quadrature encoder is attached to the motor, producing 8192 phase edges per revolution. With a velocity predivider of ÷1 (VELDIV is clear) and clocking on both PhA and PhB edges, this results in 81,920 pulses per second (the motor turns 10 times per second). If the timer were clocked at 10,000 Hz, and the load value was 2,500 (¼ of a second), it would count 20,480 pulses per update. Using the above equation:

$$\text{rpm} = (10000 * 1 * 20480 * 60) \div (2500 * 2048 * 4) = 600 \text{ rpm}$$

Now, consider that the motor is sped up to 3000 rpm. This results in 409,600 pulses per second, or 102,400 every ¼ of a second. Again, the above equation gives:

$$\text{rpm} = (10000 * 1 * 102400 * 60) \div (2500 * 2048 * 4) = 3000 \text{ rpm}$$

Care must be taken when evaluating this equation because intermediate values may exceed the capacity of a 32-bit integer. In the above examples, the clock is 10,000 and the divider is 2,500; both could be predivided by 100 (at compile time if they are constants) and therefore be 100 and 25. In fact, if they were compile-time constants, they could also be reduced to a simple multiply by 4, cancelled by the ÷4 for the edge-count factor.

**Important:** Reducing constant factors at compile time is the best way to control the intermediate values of this equation and reduce the processing requirement of computing this equation.

The division can be avoided by selecting a timer load value such that the divisor is a power of 2; a simple shift can therefore be done in place of the division. For encoders with a power of 2 pulses per revolution, the load value can be a power of 2. For other encoders, a load value must be selected such that the product is very close to a power of 2. For example, a 100 pulse-per-revolution encoder

could use a load value of 82, resulting in 32,800 as the divisor, which is 0.09% above  $2^{14}$ . In this case a shift by 15 would be an adequate approximation of the divide in most cases. If absolute accuracy were required, the microcontroller's divide instruction could be used.

The QEI module can produce a controller interrupt on several events: phase error, direction change, reception of the index pulse, and expiration of the velocity timer. Standard masking, raw interrupt status, interrupt status, and interrupt clear capabilities are provided.

## 26.4 Initialization and Configuration

The following example shows how to configure the Quadrature Encoder module to read back an absolute position:

1. Enable the QEI clock using the **RCGCQEI** register in the System Control module (see page 396).
2. Enable the clock to the appropriate GPIO module via the **RCGCGPIO** register in the System Control module (see page 380).
3. In the GPIO module, enable the appropriate pins for their alternate function using the **GPIOAFSEL** register. To determine which GPIOs to configure, see Table 28-4 on page 1680.
4. Configure the **PMC<sub>n</sub>** fields in the **GPIOPCTL** register to assign the QEI signals to the appropriate pins (see page 779 and Table 28-5 on page 1693).
5. Configure the quadrature encoder to capture edges on both signals and maintain an absolute position by resetting on index pulses. A 1000-line encoder with four edges per line, results in 4000 pulses per revolution; therefore, set the maximum position to 3999 (0xF9F) as the count is zero-based.
  - Write the **QEICTL** register with the value of 0x0000.0018.
  - Write the **QEIMAXPOS** register with the value of 0x0000.0F9F.
6. Enable the quadrature encoder by setting bit 0 of the **QEICTL** register.
 

**Note:** Once the QEI module has been enabled by setting the **ENABLE** bit in the **QEICTL** register, it cannot be disabled. The only way to clear the **ENABLE** bit is to reset the module using the **Quadrature Encoder Interface Software Reset (SRQEI)** register.
7. Delay until the encoder position is required.
8. Read the encoder position by reading the **QEI Position (QEIPOS)** register value.

**Note:** If the application requires the quadrature encoder to have a specific initial position, this value must be programmed in the **QEIPOS** register after the quadrature encoder has been enabled by setting the **ENABLE** bit in the **QEICTL** register.

## 26.5 Register Map

Table 26-2 on page 1628 lists the QEI registers. The offset listed is a hexadecimal increment to the register's address, relative to the module's base address:

- QEI0: 0x4002.C000

Note that the QEI module clock must be enabled before the registers can be programmed (see page 396). There must be a delay of 3 system clocks after the QEI module clock is enabled before any QEI module registers are accessed.

**Table 26-2. QEI Register Map**

| Offset | Name      | Type | Reset       | Description                    | See page |

## 26.6 Register Descriptions

The remainder of this section lists and describes the QEI registers, in numerical order by address offset.

## Register 1: QEI Control (QEICTL), offset 0x000

This register contains the configuration of the QEI module. Separate enables are provided for the quadrature encoder and the velocity capture blocks; the quadrature encoder must be enabled in order to capture the velocity, but the velocity does not need to be captured in applications that do not need it. The phase signal interpretation, phase swap, Position Update mode, Position Reset mode, and velocity predivider are all set via this register.

**Register 4: QEI Maximum Position (QEIMAXPOS), offset 0x00C**

This register contains the maximum value of the position integrator. When moving forward, the position register resets to zero when it increments past this value. When moving in reverse, the position register resets to this value when it decrements from zero.

QEI Maximum Position (QEIMAXPOS)

QEI0 base: 0x4002.C000  
 Offset 0x00C  
 Type RW, reset 0x0000.0000

| Bit/Field | Name   | Type | Reset       | Description  |
|-----------|--------|------|-------------|--|
| 31:0      | MAXPOS | RW   | 0x0000.0000 | Maximum Position Integrator Value<br>The maximum value of the position integrator. |

**Register 5: QEI Timer Load (QEILOAD), offset 0x010**

This register contains the load value for the velocity timer. Because this value is loaded into the timer on the clock cycle after the timer is zero, this value should be one less than the number of clocks in the desired period. So, for example, to have 2000 decimal clocks per timer period, this register should contain 1999 decimal.

**Register 6: QEI Timer (QEITIME), offset 0x014**

This register contains the current value of the velocity timer. This counter does not increment when the VELEN bit in the QEICTL register is clear.

QEI Timer (QEITIME)

QEI0 base: 0x4002.C000

Offset 0x014

Type RO, reset 0x0000.0000

| Bit/Field | Name | Type | Reset       | Description  |
|-----------|------|------|-------------|--|
| 31:0      | TIME | RO   | 0x0000.0000 | Velocity Timer Current Value<br>The current value of the velocity timer. |

**Register 7: QEI Velocity Counter (QEICOUNT), offset 0x018**

This register contains the running count of velocity pulses for the current time period. Because this count is a running total, the time period to which it applies cannot be known with precision (that is, a read of this register does not necessarily correspond to the time returned by the **QEITIME** register because there is a small window of time between the two reads, during which either value may have changed). The **QEISPEED** register should be used to determine the actual encoder velocity; this register is provided for information purposes only. This counter does not increment when the **VELEN** bit in the **QEICTL** register is clear.

## Register 10: QEI Raw Interrupt Status (QEIRIS), offset 0x024

This register provides the current set of interrupt sources that are asserted, regardless of whether they cause an interrupt to be asserted to the controller (configured through the **QEIINTEN** register). If a bit is set, the latched event has occurred; if a bit is clear, the event in question has not occurred.

### QEI Raw Interrupt Status (QEIRIS)

|           |          |      |       | 0 An interrupt has not occurred.   |
|           |          |      |       | 1 The index pulse has occurred.  |
|           |          |      |       | This bit is cleared by writing a 1 to the INTINDEX bit in the <b>QEISC</b> register. |

## Register 11: QEI Interrupt Status and Clear (QEIISC), offset 0x028

This register provides the current set of interrupt sources that are asserted to the controller. If a bit is set, the latched event has occurred and is enabled to generate an interrupt; if a bit is clear the event in question has not occurred or is not enabled to generate an interrupt. This register is RW1C; writing a 1 to a bit position clears the bit and the corresponding interrupt reason.

### QEI Interrupt Status and Clear (QEIISC)

QEI0 base: 0x4002.C000

Offset 0x028

Type RW1C, reset 0x0000.0000

## 27 Pin Diagram

The TM4C129CNCZAD microcontroller pin diagram is shown below.

Each GPIO signal is identified by its GPIO port unless it defaults to an alternate function on reset. In this case, the GPIO port name is followed by the default alternate function. To see a complete list of possible functions for each pin, see Table 28-5 on page 1693.

**Figure 27-1. 212-Ball BGA Package Pin Diagram (Top View)**

## 28 Signal Tables

The following tables list the signals available for each pin. Signals are configured as GPIOs on reset, except for those noted below. Use the **GPIOAMSEL** register (see page 778) to select analog mode. For a GPIO pin to be used for an alternate digital function, the corresponding bit in the **GPIOAFSEL** register (see page 762) must be set. Further pin muxing options are provided through the  $PMC_x$  bit field in the **GPIOPCTL** register (see page 779), which selects one of several available peripheral functions for that GPIO.

**Important:** Table 10-1 on page 732 shows special consideration GPIO pins. Most GPIO pins are configured as GPIOs and tri-stated by default (**GPIOAFSEL**=0, **GIODEN**=0, **GPIOPDR**=0, **GPIOPUR**=0, and **GPIOPCTL**=0). Special consideration pins may be programmed to a non-GPIO function or may have special commit controls out of reset. In addition, a Power-On-Reset ( $\overline{POR}$ ) returns these GPIO to their original special consideration state.

**Table 28-1. GPIO Pins With Special Considerations**

| GPIO Pins | Default Reset State | GPIOAFSEL | GIODEN | GPIOPDR | GPIOPUR | GPIOPCTL | GPIOCR |
|-----------|---------------------|-----------|--------|---------|---------|----------|--------|
| PC[3:0]   | JTAG/SWD            | 1         | 1      | 0       | 1       | 0x1      | 0      |
| PD[7]     | GPIO <sup>a</sup>   | 0         | 0      | 0       | 0       | 0x0      | 0      |
| PE[7]     | GPIO <sup>a</sup>   | 0         | 0      | 0       | 0       | 0x0      | 0      |

a. This pin is configured as a GPIO by default but is locked and can only be reprogrammed by unlocking the pin in the **GPIOLOCK** register and uncommitting it by setting the **GPIOCR** register.

Table 28-2 on page 1647 shows the pin-to-signal-name mapping, including functional characteristics of the signals. Each possible alternate analog and digital function is listed for each pin.

Table 28-3 on page 1664 lists the signals in alphabetical order by signal name. If it is possible for a signal to be on multiple pins, each possible pin assignment is listed. The "Pin Mux" column indicates the GPIO and the encoding needed in the  $PMC_x$  bit field in the **GPIOPCTL** register.

Table 28-4 on page 1680 groups the signals by functionality, except for GPIOs. If it is possible for a signal to be on multiple pins, each possible pin assignment is listed.

Table 28-5 on page 1693 lists the GPIO pins and their analog and digital alternate functions. The  $A_{INx}$  analog signals go through an isolation circuit before reaching their circuitry. These signals are configured by clearing the corresponding **DEN** bit in the **GPIO Digital Enable (GIODEN)** register and setting the corresponding **AMSEL** bit in the **GPIO Analog Mode Select (GPIOAMSEL)** register. Other analog signals are 3.3-V tolerant and are connected directly to their circuitry ( $C0-$ ,  $C0+$ ,  $C1-$ ,  $C1+$ ,  $C2-$ ,  $C2+$ ,  $USB0VBUS$ ,  $USB0ID$ ). These signals are configured by clearing the **DEN** bit in the **GPIO Digital Enable (GIODEN)** register. The digital signals are enabled by setting the appropriate bit in the **GPIO Alternate Function Select (GPIOAFSEL)** and **GIODEN** registers and configuring the  $PMC_x$  bit field in the **GPIO Port Control (GPIOPCTL)** register to the numeric encoding shown in the table below. Table entries that are shaded gray are the default values for the corresponding GPIO pin.

Table 28-6 on page 1698 lists the signals based on number of possible pin assignments. This table can be used to plan how to configure the pins for a particular functionality. Application Note AN01274 Configuring Tiva™ C Series Microcontrollers with Pin Multiplexing provides an overview of the pin muxing implementation, an explanation of how a system designer defines a pin configuration, and examples of the pin configuration process.

**Note:** All digital inputs are Schmitt triggered.

## 28.1 Signals by Pin Number

**Table 28-2. Signals by Pin Number**

| Pin Number | Pin Name  | Pin Type | Buffer Type | Description  |
|------------|-----------|----------|-------------|--|
| A1         | GND       | -        | Power       | Ground reference for logic and I/O pins.   |
| A2         | GND       | -        | Power       | Ground reference for logic and I/O pins.   |
| A4         | PD4       | I/O      | TTL         | GPIO port D bit 4.   |
|            | AIN7      | I        | Analog      | Analog-to-digital converter input 7.   |
|            | SSI1XDAT2 | I/O      | TTL         | SSI Module 1 Bi-directional Data Pin 2.  |
|            | T3CCP0    | I/O      | TTL         | 16/32-Bit Timer 3 Capture/Compare/PWM 0.   |
| A5         | U2Rx      | I        | TTL         | UART module 2 receive.   |
|            | PE4       | I/O      | TTL         | GPIO port E bit 4.   |
|            | AIN9      | I        | Analog      | Analog-to-digital converter input 9.   |
|            | SSI1XDAT0 | I/O      | TTL         | SSI Module 1 Bi-directional Data Pin 0 (SSI1TX in Legacy SSI Mode).  |
| A7         | U1RI      | I        | TTL         | UART module 1 Ring Indicator modem status input signal.  |
|            | PE6       | I/O      | TTL         | GPIO port E bit 6.   |
|            | AIN20     | I        | Analog      | Analog-to-digital converter input 20.  |
|            | I2C9SCL   | I/O      | OD          | I <sup>2</sup> C module 9 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
| A8         | U0CTS     | I        | TTL         | UART module 0 Clear To Send modem flow control input signal.   |
|            | PP7       | I/O      | TTL         | GPIO port P bit 7.   |
| A10        | AIN22     | I        | Analog      | Analog-to-digital converter input 22.  |
|            | PN4       | I/O      | TTL         | GPIO port N bit 4.   |
|            | EPI0S34   | I/O      | TTL         | EPI module 0 signal 34.  |
|            | I2C2SDA   | I/O      | OD          | I <sup>2</sup> C module 2 data.  |
|            | U1DTR     | O        | TTL         | UART module 1 Data Terminal Ready modem status input signal.   |
| A11        | U3RTS     | O        | TTL         | UART module 3 Request to Send modem flow control output line.  |
|            | PN2       | I/O      | TTL         | GPIO port N bit 2.   |
|            | EPI0S29   | I/O      | TTL         | EPI module 0 signal 29.  |
|            | U1DCD     | I        | TTL         | UART module 1 Data Carrier Detect modem status input signal.   |
| A13        | U2RTS     | O        | TTL         | UART module 2 Request to Send modem flow control output line.  |
|            | PQ4       | I/O      | TTL         | GPIO port Q bit 4.   |
|            | DIVSCLK   | O        | TTL         | An optionally divided reference clock output based on a selected clock source. Note that this signal is not synchronized to the System Clock.    |
| A14        | U1Rx      | I        | TTL         | UART module 1 receive.   |
|            | PS3       | I/O      | TTL         | GPIO port S bit 3.   |
|            | M0FAULT3  | I        | TTL         | Motion Control Module 0 PWM Fault 3.   |
|            | T3CCP1    | I/O      | TTL         | 16/32-Bit Timer 3 Capture/Compare/PWM 1.   |

Table 28-2. Signals by Pin Number (continued)

| Pin Number | Pin Name  | Pin Type | Buffer Type | Description   |
|------------|-----------|----------|-------------|---|
| A16        | PB0       | I/O      | TTL         | GPIO port B bit 0.  |
|            | CAN1Rx    | I        | TTL         | CAN module 1 receive.   |
|            | I2C5SCL   | I/O      | OD          | I <sup>2</sup> C module 5 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.  |
|            | T4CCP0    | I/O      | TTL         | 16/32-Bit Timer 4 Capture/Compare/PWM 0.  |
|            | U1Rx      | I        | TTL         | UART module 1 receive.  |
|            | USB0ID    | I        | Analog      | This signal senses the state of the USB ID signal. The USB PHY enables an integrated pull-up, and an external element (USB connector) indicates the initial state of the USB controller (pulled down is the A side of the cable and pulled up is the B side). |
| A17        | PB2       | I/O      | TTL         | GPIO port B bit 2.  |
|            | EPI0S27   | I/O      | TTL         | EPI module 0 signal 27.   |
|            | I2C0SCL   | I/O      | OD          | I <sup>2</sup> C module 0 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.  |
|            | T5CCP0    | I/O      | TTL         | 16/32-Bit Timer 5 Capture/Compare/PWM 0.  |
|            | USB0STP   | O        | TTL         | Asserted by the USB controller to signal the end of a USB transmit packet or register write operation.  |
| A18        | GND       | -        | Power       | Ground reference for logic and I/O pins.  |
| A19        | GND       | -        | Power       | Ground reference for logic and I/O pins.  |
| B1         | GND       | -        | Power       | Ground reference for logic and I/O pins.  |
| B2         | PD7       | I/O      | TTL         | GPIO port D bit 7.  |
|            | AIN4      | I        | Analog      | Analog-to-digital converter input 4.  |
|            | NMI       | I        | TTL         | Non-maskable interrupt.   |
|            | SSI2XDAT2 | I/O      | TTL         | SSI Module 2 Bi-directional Data Pin 2.   |
|            | T4CCP1    | I/O      | TTL         | 16/32-Bit Timer 4 Capture/Compare/PWM 1.  |
|            | U2CTS     | I        | TTL         | UART module 2 Clear To Send modem flow control input signal.  |
|            | USB0PFLT  | I        | TTL         | Optionally used in Host mode by an external power source to indicate an error state by that power source.   |
| B3         | PD6       | I/O      | TTL         | GPIO port D bit 6.  |
|            | AIN5      | I        | Analog      | Analog-to-digital converter input 5.  |
|            | SSI2XDAT3 | I/O      | TTL         | SSI Module 2 Bi-directional Data Pin 3.   |
|            | T4CCP0    | I/O      | TTL         | 16/32-Bit Timer 4 Capture/Compare/PWM 0.  |
|            | U2RTS     | O        | TTL         | UART module 2 Request to Send modem flow control output line.   |
|            | USB0EPEN  | O        | TTL         | Optionally used in Host mode to control an external power source to supply power to the USB bus.  |
| B4         | PD5       | I/O      | TTL         | GPIO port D bit 5.  |
|            | AIN6      | I        | Analog      | Analog-to-digital converter input 6.  |
|            | SSI1XDAT3 | I/O      | TTL         | SSI Module 1 Bi-directional Data Pin 3.   |
|            | T3CCP1    | I/O      | TTL         | 16/32-Bit Timer 3 Capture/Compare/PWM 1.  |
|            | U2Tx      | O        | TTL         | UART module 2 transmit.   |
| B5         | PE5       | I/O      | TTL         | GPIO port E bit 5.  |
|            | AIN8      | I        | Analog      | Analog-to-digital converter input 8.  |
|            | SSI1XDAT1 | I/O      | TTL         | SSI Module 1 Bi-directional Data Pin 1 (SSI1RX in Legacy SSI Mode).   |

Table 28-2. Signals by Pin Number (continued)

| Pin Number | Pin Name | Pin Type | Buffer Type | Description  |
|------------|----------|----------|-------------|--|
| B6         | PB5      | I/O      | TTL         | GPIO port B bit 5.   |
|            | AIN11    | I        | Analog      | Analog-to-digital converter input 11.  |
|            | I2C5SDA  | I/O      | OD          | I <sup>2</sup> C module 5 data.  |
|            | SSI1C1k  | I/O      | TTL         | SSI module 1 clock.  |
|            | U0RTS    | O        | TTL         | UART module 0 Request to Send modem flow control output signal.  |
| B7         | PE7      | I/O      | TTL         | GPIO port E bit 7.   |
|            | AIN21    | I        | Analog      | Analog-to-digital converter input 21.  |

Table 28-2. Signals by Pin Number (continued)

| Pin Number | Pin Name  | Pin Type | Buffer Type | Description  |
|------------|-----------|----------|-------------|--|
| B16        | PB1       | I/O      | TTL         | GPIO port B bit 1.   |
|            | CAN1Tx    | O        | TTL         | CAN module 1 transmit.   |
|            | I2C5SDA   | I/O      | OD          | I <sup>2</sup> C module 5 data.  |
|            | T4CCP1    | I/O      | TTL         | 16/32-Bit Timer 4 Capture/Compare/PWM 1.   |
|            | U1Tx      | O        | TTL         | UART module 1 transmit.  |
|            | USB0VBUS  | I/O      | Analog      | This signal is used during the session request protocol. This signal allows the USB PHY to both sense the voltage level of VBUS, and pull up VBUS momentarily during VBUS pulsing. |
| B17        | PB3       | I/O      | TTL         | GPIO port B bit 3.   |
|            | EPI0S28   | I/O      | TTL         | EPI module 0 signal 28.  |
|            | I2C0SDA   | I/O      | OD          | I <sup>2</sup> C module 0 data.  |
|            | T5CCP1    | I/O      | TTL         | 16/32-Bit Timer 5 Capture/Compare/PWM 1.   |
|            | USB0CLK   | O        | TTL         | 60-MHz clock to the external PHY.  |
| B18        | PL7       | I/O      | TTL         | GPIO port L bit 7.   |
|            | T1CCP1    | I/O      | TTL         | 16/32-Bit Timer 1 Capture/Compare/PWM 1.   |
|            | USB0DM    | I/O      | Analog      | Bidirectional differential data pin (D- per USB specification) for USB0.   |
| B19        | GND       | -        | Power       | Ground reference for logic and I/O pins.   |
| C1         | PD1       | I/O      | TTL         | GPIO port D bit 1.   |
|            | AIN14     | I        | Analog      | Analog-to-digital converter input 14.  |
|            | C1o       | O        | TTL         | Analog comparator 1 output.  |
|            | I2C7SDA   | I/O      | OD          | I <sup>2</sup> C module 7 data.  |
|            | SSI2XDAT0 | I/O      | TTL         | SSI Module 2 Bi-directional Data Pin 0 (SSI2TX in Legacy SSI Mode).  |
|            | T0CCP1    | I/O      | TTL         | 16/32-Bit Timer 0 Capture/Compare/PWM 1.   |
| C2         | PD0       | I/O      | TTL         | GPIO port D bit 0.   |
|            | AIN15     | I        | Analog      | Analog-to-digital converter input 15.  |
|            | C0o       | O        | TTL         | Analog comparator 0 output.  |
|            | I2C7SCL   | I/O      | OD          | I <sup>2</sup> C module 7 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.                                   |
|            | SSI2XDAT1 | I/O      | TTL         | SSI Module 2 Bi-directional Data Pin 1 (SSI2RX in Legacy SSI Mode).  |
|            | T0CCP0    | I/O      | TTL         | 16/32-Bit Timer 0 Capture/Compare/PWM 0.   |
| C5         | NC        | -        | -           | No connect. Leave the pin electrically unconnected/isolated.   |
| C6         | PB4       | I/O      | TTL         | GPIO port B bit 4.   |
|            | AIN10     | I        | Analog      | Analog-to-digital converter input 10.  |
|            | I2C5SCL   | I/O      | OD          | I <sup>2</sup> C module 5 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.                                   |
|            | SSI1Fss   | I/O      | TTL         | SSI module 1 frame signal.   |
|            | U0CTS     | I        | TTL         | UART module 0 Clear To Send modem flow control input signal.   |
| C8         | PJ0       | I/O      | TTL         | GPIO port J bit 0.   |
|            | U3Rx      | I        | TTL         | UART module 3 receive.   |

Table 28-2. Signals by Pin Number (continued)

| Pin Number | Pin Name  | Pin Type | Buffer Type | Description   |
|------------|-----------|----------|-------------|---|
| C10        | PN0       | I/O      | TTL         | GPIO port N bit 0.  |
|            | U1RTS     | O        | TTL         | UART module 1 Request to Send modem flow control output line.   |
| C12        | PP3       | I/O      | TTL         | GPIO port P bit 3.  |
|            | EPI0S30   | I/O      | TTL         | EPI module 0 signal 30.   |
|            | RTCCLK    | O        | TTL         | Buffered version of the Hibernation module's 32.768-kHz clock. This signal is not output when the part is in Hibernate mode and before being configured after power-on reset. |
|            | U0DCD     | I        | TTL         | UART module 0 Data Carrier Detect modem status input signal.  |
|            | U1CTS     | I        | TTL         | UART module 1 Clear To Send modem flow control input signal.  |
|            | USB0DIR   | O        | TTL         | Indicates that the external PHY is able to accept data from the USB controller.   |
| C14        | PC3       | I/O      | TTL         | GPIO port C bit 3.  |
|            | SWO       | O        | TTL         | JTAG TDO and SWO.   |
|            | TDO       | O        | TTL         | JTAG TDO and SWO.   |
| C15        | PC1       | I/O      | TTL         | GPIO port C bit 1.  |
|            | SWDIO     | I/O      | TTL         | JTAG TMS and SWDIO.   |
|            | TMS       | I        | TTL         | JTAG TMS and SWDIO.   |
| C18        | PL6       | I/O      | TTL         | GPIO port L bit 6.  |
|            | T1CCP0    | I/O      | TTL         | 16/32-Bit Timer 1 Capture/Compare/PWM 0.  |
|            | USB0DP    | I/O      | Analog      | Bidirectional differential data pin (D+ per USB specification) for USB0.  |
| D1         | PD3       | I/O      | TTL         | GPIO port D bit 3.  |
|            | AIN12     | I        | Analog      | Analog-to-digital converter input 12.   |
|            | I2C8SDA   | I/O      | OD          | I <sup>2</sup> C module 8 data.   |
|            | SSI2C1k   | I/O      | TTL         | SSI module 2 clock.   |
|            | T1CCP1    | I/O      | TTL         | 16/32-Bit Timer 1 Capture/Compare/PWM 1.  |
| D2         | PD2       | I/O      | TTL         | GPIO port D bit 2.  |
|            | AIN13     | I        | Analog      | Analog-to-digital converter input 13.   |
|            | C2o       | O        | TTL         | Analog comparator 2 output.   |
|            | I2C8SCL   | I/O      | OD          | I <sup>2</sup> C module 8 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.                              |
|            | SSI2Fss   | I/O      | TTL         | SSI module 2 frame signal.  |
|            | T1CCP0    | I/O      | TTL         | 16/32-Bit Timer 1 Capture/Compare/PWM 0.  |
| D6         | PP0       | I/O      | TTL         | GPIO port P bit 0.  |
|            | C2+       | I        | Analog      | Analog comparator 2 positive input.   |
|            | SSI3XDAT2 | I/O      | TTL         | SSI Module 3 Bi-directional Data Pin 2.   |
|            | T6CCP0    | I/O      | TTL         | 16/32-Bit Timer 6 Capture/Compare/PWM 0.  |
|            | U6Rx      | I        | TTL         | UART module 6 receive.  |
| D7         | PP1       | I/O      | TTL         | GPIO port P bit 1.  |
|            | C2-       | I        | Analog      | Analog comparator 2 negative input.   |
|            | SSI3XDAT3 | I/O      | TTL         | SSI Module 3 Bi-directional Data Pin 3.   |
|            | T6CCP1    | I/O      | TTL         | 16/32-Bit Timer 6 Capture/Compare/PWM 1.  |
|            | U6Tx      | O        | TTL         | UART module 6 transmit.   |

Table 28-2. Signals by Pin Number (continued)

| Pin Number | Pin Name | Pin Type | Buffer Type | Description   |
|------------|----------|----------|-------------|---|
| D8         | PP4      | I/O      | TTL         | GPIO port P bit 4.  |
|            | U0DSR    | I        | TTL         | UART module 0 Data Set Ready modem output control line.   |
|            | U3RTS    | O        | TTL         | UART module 3 Request to Send modem flow control output line.   |
|            | USB0D7   | I/O      | TTL         | USB data 7.   |
| D12        | PS0      | I/O      | TTL         | GPIO port S bit 0.  |
|            | MOFAULT0 | I        | TTL         | Motion Control Module 0 PWM Fault 0.  |
|            | T2CCP0   | I/O      | TTL         | 16/32-Bit Timer 2 Capture/Compare/PWM 0.  |
| D13        | PS1      | I/O      | TTL         | GPIO port S bit 1.  |
|            | MOFAULT1 | I        | TTL         | Motion Control Module 0 PWM Fault 1.  |
|            | T2CCP1   | I/O      | TTL         | 16/32-Bit Timer 2 Capture/Compare/PWM 1.  |
| D14        | PC2      | I/O      | TTL         | GPIO port C bit 2.  |
|            | TDI      | I        | TTL         | JTAG TDI.   |
| D18        | GNDX2    | -        | Power       | GND for the MOSC. When using a crystal clock source, this pin should be connected to digital ground along with the crystal load capacitors. When using an external oscillator, this pin should be connected to digital ground.  |
| D19        | OSC1     | O        | Analog      | Main oscillator crystal output. Leave unconnected when using a single-ended clock source.   |
| E2         | PQ1      | I/O      | TTL         | GPIO port Q bit 1.  |
|            | EPI0S21  | I/O      | TTL         | EPI module 0 signal 21.   |
|            | SSI3Fss  | I/O      | TTL         | SSI module 3 frame signal.  |
|            | T6CCP1   | I/O      | TTL         | 16/32-Bit Timer 6 Capture/Compare/PWM 1.  |
| E3         | PQ0      | I/O      | TTL         | GPIO port Q bit 0.  |
|            | EPI0S20  | I/O      | TTL         | EPI module 0 signal 20.   |
|            | SSI3C1k  | I/O      | TTL         | SSI module 3 clock.   |
|            | T6CCP0   | I/O      | TTL         | 16/32-Bit Timer 6 Capture/Compare/PWM 0.  |
| E7         | PJ1      | I/O      | TTL         | GPIO port J bit 1.  |
|            | U3Tx     | O        | TTL         | UART module 3 transmit.   |
| E10        | VDDC     | -        | Power       | Positive supply for most of the logic function, including the processor core and most peripherals. The voltage on this pin is 1.2 V and is supplied by the on-chip LDO. The VDDC pins should only be connected to each other and an external capacitor as specified in Table 29-15 on page 1721 . |
| E13        | NC       | -        | -           | No connect. Leave the pin electrically unconnected/isolated.  |
| E17        | PJ5      | I/O      | TTL         | GPIO port J bit 5.  |
|            | U3CTS    | I        | TTL         | UART module 3 Clear To Send modem flow control input signal.  |
| E18        | PT2      | I/O      | TTL         | GPIO port T bit 2.  |
|            | CAN1Rx   | I        | TTL         | CAN module 1 receive.   |
|            | T7CCP0   | I/O      | TTL         | 16/32-Bit Timer 7 Capture/Compare/PWM 0.  |
| E19        | OSC0     | I        | Analog      | Main oscillator crystal input or an external clock reference input.   |
| F1         | PB7      | I/O      | TTL         | GPIO port B bit 7.  |
|            | I2C6SDA  | I/O      | OD          | I <sup>2</sup> C module 6 data.   |
|            | T6CCP1   | I/O      | TTL         | 16/32-Bit Timer 6 Capture/Compare/PWM 1.  |

Table 28-2. Signals by Pin Number (continued)

| Pin Number | Pin Name | Pin Type | Buffer Type | Description  |
|------------|----------|----------|-------------|--|
| F2         | PB6      | I/O      | TTL         | GPIO port B bit 6.   |
|            | I2C6SCL  | I/O      | OD          | I <sup>2</sup> C module 6 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.   |
|            | T6CCP0   | I/O      | TTL         | 16/32-Bit Timer 6 Capture/Compare/PWM 0.   |
| F3         | VDDA     | -        | Power       | The positive supply for the analog circuits (ADC, Analog Comparators, etc.). These are separated from VDD to minimize the electrical noise contained on VDD from affecting the analog functions. VDDA pins must be supplied with a voltage that meets the specification in , regardless of system implementation.  |
| F4         | VREFA+   | -        | Analog      | A reference voltage used to specify the voltage at which the ADC converts to a maximum value. This pin is used in conjunction with VREFA-, which specifies the minimum value . The voltage that is applied to VREFA+ is the voltage with which an AIN <sub>n</sub> signal is converted to 4095. The VREFA+ voltage is limited to the range specified in Table 29-44 on page 1748.  |
| F10        | GND      | -        | Power       | Ground reference for logic and I/O pins.   |
| F16        | PJ3      | I/O      | TTL         | GPIO port J bit 3.   |
|            | U2CTS    | I        | TTL         | UART module 2 Clear To Send modem flow control input signal.   |
| F17        | PT3      | I/O      | TTL         | GPIO port T bit 3.   |
|            | CAN1Tx   | O        | TTL         | CAN module 1 transmit.   |
|            | T7CCP1   | I/O      | TTL         | 16/32-Bit Timer 7 Capture/Compare/PWM 1.   |
| F18        | PJ4      | I/O      | TTL         | GPIO port J bit 4.   |
|            | U3RTS    | O        | TTL         | UART module 3 Request to Send modem flow control output line.  |
| G1         | PE2      | I/O      | TTL         | GPIO port E bit 2.   |
|            | AIN1     | I        | Analog      | Analog-to-digital converter input 1.   |
|            | U1DCD    | I        | TTL         | UART module 1 Data Carrier Detect modem status input signal.   |
| G2         | PE3      | I/O      | TTL         | GPIO port E bit 3.   |
|            | AIN0     | I        | Analog      | Analog-to-digital converter input 0.   |
|            | U1DTR    | O        | TTL         | UART module 1 Data Terminal Ready modem status input signal.   |
| G4         | GNDA     | -        | Power       | The ground reference for the analog circuits (ADC, Analog Comparators, etc.). These are separated from GND to minimize the electrical noise contained on VDD from affecting the analog functions.  |
| G5         | VREFA-   | -        | Analog      | A reference voltage used to specify the input voltage at which the ADC converts to a minimum value. This pin is used in conjunction with VREFA+, which specifies the maximum value. In other words, the voltage that is applied to VREFA- is the voltage with which an AIN <sub>n</sub> signal is converted to 0, while the voltage that is applied to VREFA+ is the voltage with which an AIN <sub>n</sub> signal is converted to 4095. The VREFA- voltage is limited to the range specified in Table 29-44 on page 1748. |
| G10        | VDD      | -        | Power       | Positive supply for I/O and some logic.  |
| G15        | PM5      | I/O      | TTL         | GPIO port M bit 5.   |
|            | T4CCP1   | I/O      | TTL         | 16/32-Bit Timer 4 Capture/Compare/PWM 1.   |
|            | TMPR2    | I/O      | TTL         | Tamper signal 2.   |
|            | U0DCD    | I        | TTL         | UART module 0 Data Carrier Detect modem status input signal.   |

Table 28-2. Signals by Pin Number (continued)

| Pin Number | Pin Name  | Pin Type | Buffer Type | Description   |
|------------|-----------|----------|-------------|---|
| G16        | PL0       | I/O      | TTL         | GPIO port L bit 0.  |
|            | EPI0S16   | I/O      | TTL         | EPI module 0 signal 16.   |
|            | I2C2SDA   | I/O      | OD          | I <sup>2</sup> C module 2 data.   |
|            | M0FAULT3  | I        | TTL         | Motion Control Module 0 PWM Fault 3.  |
|            | USB0D0    | I/O      | TTL         | USB data 0.   |
| G18        | PL2       | I/O      | TTL         | GPIO port L bit 2.  |
|            | C0o       | O        | TTL         | Analog comparator 0 output.   |
|            | EPI0S18   | I/O      | TTL         | EPI module 0 signal 18.   |
|            | PhB0      | I        | TTL         | QEI module 0 phase B.   |
|            | USB0D2    | I/O      | TTL         | USB data 2.   |
| G19        | PL5       | I/O      | TTL         | GPIO port L bit 5.  |
|            | EPI0S33   | I/O      | TTL         | EPI module 0 signal 33.   |
|            | T0CCP1    | I/O      | TTL         | 16/32-Bit Timer 0 Capture/Compare/PWM 1.  |
|            | USB0D5    | I/O      | TTL         | USB data 5.   |
| H2         | PE1       | I/O      | TTL         | GPIO port E bit 1.  |
|            | AIN2      | I        | Analog      | Analog-to-digital converter input 2.  |
|            | U1DSR     | I        | TTL         | UART module 1 Data Set Ready modem output control line.   |
| H3         | PE0       | I/O      | TTL         | GPIO port E bit 0.  |
|            | AIN3      | I        | Analog      | Analog-to-digital converter input 3.  |
|            | U1RTS     | O        | TTL         | UART module 1 Request to Send modem flow control output line.   |
| H4         | PQ2       | I/O      | TTL         | GPIO port Q bit 2.  |
|            | EPI0S22   | I/O      | TTL         | EPI module 0 signal 22.   |
|            | SSI3XDAT0 | I/O      | TTL         | SSI Module 3 Bi-directional Data Pin 0 (SSI3TX in Legacy SSI Mode).   |
|            | T7CCP0    | I/O      | TTL         | 16/32-Bit Timer 7 Capture/Compare/PWM 0.  |
| H9         | VDD       | -        | Power       | Positive supply for I/O and some logic.   |
| H10        | GND       | -        | Power       | Ground reference for logic and I/O pins.  |
| H11        | GND       | -        | Power       | Ground reference for logic and I/O pins.  |
| H12        | GND       | -        | Power       | Ground reference for logic and I/O pins.  |
| H16        | VDDC      | -        | Power       | Positive supply for most of the logic function, including the processor core and most peripherals. The voltage on this pin is 1.2 V and is supplied by the on-chip LDO. The VDDC pins should only be connected to each other and an external capacitor as specified in Table 29-15 on page 1721 . |
| H17        | PJ2       | I/O      | TTL         | GPIO port J bit 2.  |
|            | U2RTS     | O        | TTL         | UART module 2 Request to Send modem flow control output line.   |
| H18        | PL4       | I/O      | TTL         | GPIO port L bit 4.  |
|            | EPI0S26   | I/O      | TTL         | EPI module 0 signal 26.   |
|            | T0CCP0    | I/O      | TTL         | 16/32-Bit Timer 0 Capture/Compare/PWM 0.  |
|            | USB0D4    | I/O      | TTL         | USB data 4.   |

Table 28-2. Signals by Pin Number (continued)

| Pin Number | Pin Name | Pin Type | Buffer Type | Description  |
|------------|----------|----------|-------------|--|
| H19        | PL1      | I/O      | TTL         | GPIO port L bit 1.   |
|            | EPI0S17  | I/O      | TTL         | EPI module 0 signal 17.  |
|            | I2C2SCL  | I/O      | OD          | I <sup>2</sup> C module 2 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
|            | PhA0     | I        | TTL         | QEI module 0 phase A.  |
|            | USB0D1   | I/O      | TTL         | USB data 1.  |
| J1         | PK0      | I/O      | TTL         | GPIO port K bit 0.   |
|            | AIN16    | I        | Analog      | Analog-to-digital converter input 16.  |
|            | EPI0S0   | I/O      | TTL         | EPI module 0 signal 0.   |
|            | U4Rx     | I        | TTL         | UART module 4 receive.   |
| J2         | PK1      | I/O      | TTL         | GPIO port K bit 1.   |
|            | AIN17    | I        | Analog      | Analog-to-digital converter input 17.  |
|            | EPI0S1   | I/O      | TTL         | EPI module 0 signal 1.   |
|            | U4Tx     | O        | TTL         | UART module 4 transmit.  |
| J8         | VDD      | -        | Power       | Positive supply for I/O and some logic.  |
| J9         | VDD      | -        | Power       | Positive supply for I/O and some logic.  |
| J10        | VDD      | -        | Power       | Positive supply for I/O and some logic.  |
| J11        | GND      | -        | Power       | Ground reference for logic and I/O pins.   |
| J12        | GND      | -        | Power       | Ground reference for logic and I/O pins.   |
| J18        | PL3      | I/O      | TTL         | GPIO port L bit 3.   |
|            | C1o      | O        | TTL         | Analog comparator 1 output.  |
|            | EPI0S19  | I/O      | TTL         | EPI module 0 signal 19.  |
|            | IDX0     | I        | TTL         | QEI module 0 index.  |
|            | USB0D3   | I/O      | TTL         | USB data 3.  |
| K1         | PK2      | I/O      | TTL         | GPIO port K bit 2.   |
|            | AIN18    | I        | Analog      | Analog-to-digital converter input 18.  |
|            | EPI0S2   | I/O      | TTL         | EPI module 0 signal 2.   |
|            | U4RTS    | O        | TTL         | UART module 4 Request to Send modem flow control output line.  |
| K2         | PK3      | I/O      | TTL         | GPIO port K bit 3.   |
|            | AIN19    | I        | Analog      | Analog-to-digital converter input 19.  |
|            | EPI0S3   | I/O      | TTL         | EPI module 0 signal 3.   |
|            | U4CTS    | I        | TTL         | UART module 4 Clear To Send modem flow control input signal.   |
| K3         | PC7      | I/O      | TTL         | GPIO port C bit 7.   |
|            | C0-      | I        | Analog      | Analog comparator 0 negative input.  |
|            | EPI0S4   | I/O      | TTL         | EPI module 0 signal 4.   |
|            | U5Tx     | O        | TTL         | UART module 5 transmit.  |
| K5         | PJ7      | I/O      | TTL         | GPIO port J bit 7.   |
|            | U4CTS    | I        | TTL         | UART module 4 Clear To Send modem flow control input signal.   |
| K6         | GND      | -        | Power       | Ground reference for logic and I/O pins.   |
| K7         | VDD      | -        | Power       | Positive supply for I/O and some logic.  |
| K8         | VDD      | -        | Power       | Positive supply for I/O and some logic.  |

Table 28-2. Signals by Pin Number (continued)

| Pin Number | Pin Name  | Pin Type | Buffer Type | Description  |
|------------|-----------|----------|-------------|--|
| K9         | GND       | -        | Power       | Ground reference for logic and I/O pins.   |
| K10        | GND       | -        | Power       | Ground reference for logic and I/O pins.   |
| K11        | VDD       | -        | Power       | Positive supply for I/O and some logic.  |
| K12        | VDD       | -        | Power       | Positive supply for I/O and some logic.  |
| K13        | GND       | -        | Power       | Ground reference for logic and I/O pins.   |
| K14        | GND       | -        | Power       | Ground reference for logic and I/O pins.   |
| K15        | PG5       | I/O      | TTL         | GPIO port G bit 5.   |
|            | I2C3SDA   | I/O      | OD          | I <sup>2</sup> C module 3 data.  |
|            | SSI2XDAT0 | I/O      | TTL         | SSI Module 2 Bi-directional Data Pin 0 (SSI2TX in Legacy SSI Mode).  |
|            | U0RTS     | O        | TTL         | UART module 0 Request to Send modem flow control output signal.  |
| K17        | PG4       | I/O      | TTL         | GPIO port G bit 4.   |
|            | I2C3SCL   | I/O      | OD          | I <sup>2</sup> C module 3 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
|            | SSI2XDAT1 | I/O      | TTL         | SSI Module 2 Bi-directional Data Pin 1 (SSI2RX in Legacy SSI Mode).  |
|            | U0CTS     | I        | TTL         | UART module 0 Clear To Send modem flow control input signal.   |
| K18        | PM0       | I/O      | TTL         | GPIO port M bit 0.   |
|            | EPI0S15   | I/O      | TTL         | EPI module 0 signal 15.  |
|            | T2CCP0    | I/O      | TTL         | 16/32-Bit Timer 2 Capture/Compare/PWM 0.   |
| K19        | PM1       | I/O      | TTL         | GPIO port M bit 1.   |
|            | EPI0S14   | I/O      | TTL         | EPI module 0 signal 14.  |
|            | T2CCP1    | I/O      | TTL         | 16/32-Bit Timer 2 Capture/Compare/PWM 1.   |
| L2         | PC6       | I/O      | TTL         | GPIO port C bit 6.   |
|            | C0+       | I        | Analog      | Analog comparator 0 positive input.  |
|            | EPI0S5    | I/O      | TTL         | EPI module 0 signal 5.   |
|            | U5Rx      | I        | TTL         | UART module 5 receive.   |
| L8         | GND       | -        | Power       | Ground reference for logic and I/O pins.   |
| L9         | GND       | -        | Power       | Ground reference for logic and I/O pins.   |
| L10        | VDD       | -        | Power       | Positive supply for I/O and some logic.  |
| L11        | VDD       | -        | Power       | Positive supply for I/O and some logic.  |
| L12        | VDD       | -        | Power       | Positive supply for I/O and some logic.  |
| L18        | PM2       | I/O      | TTL         | GPIO port M bit 2.   |
|            | EPI0S13   | I/O      | TTL         | EPI module 0 signal 13.  |
|            | T3CCP0    | I/O      | TTL         | 16/32-Bit Timer 3 Capture/Compare/PWM 0.   |
| L19        | PM3       | I/O      | TTL         | GPIO port M bit 3.   |
|            | EPI0S12   | I/O      | TTL         | EPI module 0 signal 12.  |
|            | T3CCP1    | I/O      | TTL         | 16/32-Bit Timer 3 Capture/Compare/PWM 1.   |

| Pin Number | Pin Name                | Pin Type | Buffer Type | Description   |
|------------|-------------------------|----------|-------------|---|
| M1         | PC5                     | I/O      | TTL         | GPIO port C bit 5.  |
|            | C1+                     | I        | Analog      | Analog comparator 1 positive input.   |
|            | EPI0S6                  | I/O      | TTL         | EPI module 0 signal 6.  |
|            | RTCCLK                  | O        | TTL         | Buffered version of the Hibernation module's 32.768-kHz clock. This signal is not output when the part is in Hibernate mode and before being configured after power-on reset. |
|            | T7CCP1                  | I/O      | TTL         | 16/32-Bit Timer 7 Capture/Compare/PWM 1.  |
|            | U7Tx                    | O        | TTL         | UART module 7 transmit.   |
| M2         | PC4                     | I/O      | TTL         | GPIO port C bit 4.  |
|            | C1-                     | I        | Analog      | Analog comparator 1 negative input.   |
|            | EPI0S7                  | I/O      | TTL         | EPI module 0 signal 7.  |
|            | T7CCP0                  | I/O      | TTL         | 16/32-Bit Timer 7 Capture/Compare/PWM 0.  |
|            | U7Rx                    | I        | TTL         | UART module 7 receive.  |
| M3         | PQ7                     | I/O      | TTL         | GPIO port Q bit 7.  |
|            | U1RI                    | I        | TTL         | UART module 1 Ring Indicator modem status input signal.   |
| M4         | PQ3                     | I/O      | TTL         | GPIO port Q bit 3.  |
|            | EPI0S23                 | I/O      | TTL         | EPI module 0 signal 23.   |
|            | SSI3XDAT1               | I/O      | TTL         | SSI Module 3 Bi-directional Data Pin 1 (SSI3RX in Legacy SSI Mode).   |
|            | T7CCP1                  | I/O      | TTL         | 16/32-Bit Timer 7 Capture/Compare/PWM 1.  |
| M8         | GND                     | -        | Power       | Ground reference for logic and I/O pins.  |
| M9         | GND                     | -        | Power       | Ground reference for logic and I/O pins.  |
| M10        | GND                     | -        | Power       | Ground reference for logic and I/O pins.  |
| M11        | VDD                     | -        | Power       | Positive supply for I/O and some logic.   |
| M12        | VDD                     | -        | Power       | Positive supply for I/O and some logic.   |
| M16        | PG3                     | I/O      | TTL         | GPIO port G bit 3.  |
|            | I2C2SDA                 | I/O      | OD          | I <sup>2</sup> C module 2 data.   |
|            | SSI2XDAT2               | I/O      | TTL         | SSI Module 2 Bi-directional Data Pin 2.   |
| M17        | $\overline{\text{HIB}}$ | O        | TTL         | An output that indicates the processor is in Hibernate mode.  |
| M18        | PM4                     | I/O      | TTL         | GPIO port M bit 4.  |
|            | T4CCP0                  | I/O      | TTL         | 16/32-Bit Timer 4 Capture/Compare/PWM 0.  |
|            | TMPR3                   | I/O      | TTL         | Tamper signal 3.  |
|            | U0CTS                   | I        | TTL         | UART module 0 Clear To Send modem flow control input signal.  |
| N1         | PJ6                     | I/O      | TTL         | GPIO port J bit 6.  |
|            | U4RTS                   | O        | TTL         | UART module 4 Request to Send modem flow control output line.   |
| N2         | PR2                     | I/O      | TTL         | GPIO port R bit 2.  |
|            | I2C2SCL                 | I/O      | OD          | I <sup>2</sup> C module 2 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.                              |
|            | M0PWM2                  | O        | TTL         | Motion Control Module 0 PWM 2. This signal is controlled by Module 0 PWM Generator 1.   |

Table 28-2. Signals by Pin Number (continued)

| Pin Number | Pin Name | Pin Type | Buffer Type | Description  |
|------------|----------|----------|-------------|--|
| N4         | PR1      | I/O      | TTL         | GPIO port R bit 1.   |
|            | I2C1SDA  | I/O      | OD          | I <sup>2</sup> C module 1 data.  |
|            | M0PWM1   | O        | TTL         | Motion Control Module 0 PWM 1. This signal is controlled by Module 0 PWM Generator 0.  |
|            | U4Rx     | I        | TTL         | UART module 4 receive.   |
| N5         | PR0      | I/O      | TTL         | GPIO port R bit 0.   |
|            | I2C1SCL  | I/O      | OD          | I <sup>2</sup> C module 1 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
|            | M0PWM0   | O        | TTL         | Motion Control Module 0 PWM 0. This signal is controlled by Module 0 PWM Generator 0.  |
|            | U4Tx     | O        | TTL         | UART module 4 transmit.  |
| N10        | GND      | -        | Power       | Ground reference for logic and I/O pins.   |
| N15        | PG0      | I/O      | TTL         | GPIO port G bit 0.   |
|            | EPI0S11  | I/O      | TTL         | EPI module 0 signal 11.  |
|            | I2C1SCL  | I/O      | OD          | I <sup>2</sup> C module 1 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
|            | M0PWM4   | O        | TTL         | Motion Control Module 0 PWM 4. This signal is controlled by Module 0 PWM Generator 2.  |
| N16        | VDD      | -        | Power       | Positive supply for I/O and some logic.  |
| N18        | PM7      | I/O      | TTL         | GPIO port M bit 7.   |
|            | T5CCP1   | I/O      | TTL         | 16/32-Bit Timer 5 Capture/Compare/PWM 1.   |
|            | TMPR0    | I/O      | TTL         | Tamper signal 0.   |
|            | U0RI     | I        | TTL         | UART module 0 Ring Indicator modem status input signal.  |
| N19        | PM6      | I/O      | TTL         | GPIO port M bit 6.   |
|            | T5CCP0   | I/O      | TTL         | 16/32-Bit Timer 5 Capture/Compare/PWM 0.   |
|            | TMPR1    | I/O      | TTL         | Tamper signal 1.   |
|            | U0DSR    | I        | TTL         | UART module 0 Data Set Ready modem output control line.  |
| P2         | PR5      | I/O      | TTL         | GPIO port R bit 5.   |
|            | I2C3SDA  | I/O      | OD          | I <sup>2</sup> C module 3 data.  |
|            | M0PWM5   | O        | TTL         | Motion Control Module 0 PWM 5. This signal is controlled by Module 0 PWM Generator 2.  |
|            | T0CCP1   | I/O      | TTL         | 16/32-Bit Timer 0 Capture/Compare/PWM 1.   |
|            | U1Rx     | I        | TTL         | UART module 1 receive.   |
| P3         | PR4      | I/O      | TTL         | GPIO port R bit 4.   |
|            | I2C3SCL  | I/O      | OD          | I <sup>2</sup> C module 3 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
|            | M0PWM4   | O        | TTL         | Motion Control Module 0 PWM 4. This signal is controlled by Module 0 PWM Generator 2.  |
|            | T0CCP0   | I/O      | TTL         | 16/32-Bit Timer 0 Capture/Compare/PWM 0.   |
| P4         | PH0      | I/O      | TTL         | GPIO port H bit 0.   |
|            | EPI0S0   | I/O      | TTL         | EPI module 0 signal 0.   |
|            | U0RTS    | O        | TTL         | UART module 0 Request to Send modem flow control output signal.  |
| P10        | VDD      | -        | Power       | Positive supply for I/O and some logic.  |
| P16        | GND      | -        | Power       | Ground reference for logic and I/O pins.   |

Table 28-2. Signals by Pin Number (continued)

| Pin Number | Pin Name  | Pin Type | Buffer Type | Description  |
|------------|-----------|----------|-------------|--|
| P17        | VDD       | -        | Power       | Positive supply for I/O and some logic.  |
| P18        | RST       | I        | TTL         | System reset input.  |
| P19        | VBAT      | -        | Power       | Power source for the Hibernation module. It is normally connected to the positive terminal of a battery and serves as the battery backup/Hibernation module power-source supply.   |
| R1         | PH2       | I/O      | TTL         | GPIO port H bit 2.   |
|            | EPI0S2    | I/O      | TTL         | EPI module 0 signal 2.   |
|            | U0DCD     | I        | TTL         | UART module 0 Data Carrier Detect modem status input signal.   |
| R2         | PH1       | I/O      | TTL         | GPIO port H bit 1.   |
|            | EPI0S1    | I/O      | TTL         | EPI module 0 signal 1.   |
|            | U0CTS     | I        | TTL         | UART module 0 Clear To Send modem flow control input signal.   |
| R3         | PH4       | I/O      | TTL         | GPIO port H bit 4.   |
|            | U0DTR     | O        | TTL         | UART module 0 Data Terminal Ready modem status input signal.   |
| R7         | PA7       | I/O      | TTL         | GPIO port A bit 7.   |
|            | EPI0S9    | I/O      | TTL         | EPI module 0 signal 9.   |
|            | I2C6SDA   | I/O      | OD          | I <sup>2</sup> C module 6 data.  |
|            | SSI0XDAT3 | I/O      | TTL         | SSI Module 0 Bi-directional Data Pin 3.  |
|            | T3CCP1    | I/O      | TTL         | 16/32-Bit Timer 3 Capture/Compare/PWM 1.   |
|            | U2Tx      | O        | TTL         | UART module 2 transmit.  |
|            | USB0EPEN  | O        | TTL         | Optionally used in Host mode to control an external power source to supply power to the USB bus.   |
| R10        | USB0PFLT  | I        | TTL         | Optionally used in Host mode by an external power source to indicate an error state by that power source.  |
|            | PR7       | I/O      | TTL         | GPIO port R bit 7.   |
|            | I2C4SDA   | I/O      | OD          | I <sup>2</sup> C module 4 data.  |
|            | M0PWM7    | O        | TTL         | Motion Control Module 0 PWM 7. This signal is controlled by Module 0 PWM Generator 3.  |
| R13        | T1CCP1    | I/O      | TTL         | 16/32-Bit Timer 1 Capture/Compare/PWM 1.   |
|            | PS7       | I/O      | TTL         | GPIO port S bit 7.   |
| R17        | T5CCP1    | I/O      | TTL         | 16/32-Bit Timer 5 Capture/Compare/PWM 1.   |
|            | GND       | -        | Power       | Ground reference for logic and I/O pins.   |
| R18        | GNDX      | -        | Power       | GND for the Hibernation oscillator. When using a crystal clock source, this pin should be connected to digital ground along with the crystal load capacitors. When using an external oscillator, this pin should be connected to digital ground. |
| T1         | PH3       | I/O      | TTL         | GPIO port H bit 3.   |
|            | EPI0S3    | I/O      | TTL         | EPI module 0 signal 3.   |
|            | U0DSR     | I        | TTL         | UART module 0 Data Set Ready modem output control line.  |
| T2         | PH5       | I/O      | TTL         | GPIO port H bit 5.   |
|            | U0RI      | I        | TTL         | UART module 0 Ring Indicator modem status input signal.  |

Table 28-2. Signals by Pin Number (continued)

| Pin Number | Pin Name  | Pin Type | Buffer Type | Description   |
|------------|-----------|----------|-------------|---|
| T6         | PA2       | I/O      | TTL         | GPIO port A bit 2.  |
|            | I2C8SCL   | I/O      | OD          | I <sup>2</sup> C module 8 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.                                |
|            | SSI0C1k   | I/O      | TTL         | SSI module 0 clock  |
|            | T1CCP0    | I/O      | TTL         | 16/32-Bit Timer 1 Capture/Compare/PWM 0.  |
|            | U4Rx      | I        | TTL         | UART module 4 receive.  |
| T7         | PF3       | I/O      | TTL         | GPIO port F bit 3.  |
|            | M0PWM3    | O        | TTL         | Motion Control Module 0 PWM 3. This signal is controlled by Module 0 PWM Generator 1.   |
|            | SSI3C1k   | I/O      | TTL         | SSI module 3 clock.   |
|            | TRCLK     | O        | TTL         | Trace clock.  |
| T8         | PF6       | I/O      | TTL         | GPIO port F bit 6.  |
| T12        | PN6       | I/O      | TTL         | GPIO port N bit 6.  |
|            | U4RTS     | O        | TTL         | UART module 4 Request to Send modem flow control output line.   |
| T13        | PS5       | I/O      | TTL         | GPIO port S bit 5.  |
|            | PhB0      | I        | TTL         | QEI module 0 phase B.   |
|            | T4CCP1    | I/O      | TTL         | 16/32-Bit Timer 4 Capture/Compare/PWM 1.  |
| T14        | PG1       | I/O      | TTL         | GPIO port G bit 1.  |
|            | EPI0S10   | I/O      | TTL         | EPI module 0 signal 10.   |
|            | I2C1SDA   | I/O      | OD          | I <sup>2</sup> C module 1 data.   |
|            | M0PWM5    | O        | TTL         | Motion Control Module 0 PWM 5. This signal is controlled by Module 0 PWM Generator 2.   |
| T18        | XOSC0     | I        | Analog      | Hibernation module oscillator crystal input or an external clock reference input. Note that this is either a crystal or a 32.768-kHz oscillator for the Hibernation module RTC. |
| T19        | XOSC1     | O        | Analog      | Hibernation module oscillator crystal output. Leave unconnected when using a single-ended clock source.   |
| U2         | PH6       | I/O      | TTL         | GPIO port H bit 6.  |
|            | U5Rx      | I        | TTL         | UART module 5 receive.  |
|            | U7Rx      | I        | TTL         | UART module 7 receive.  |
| U5         | PA3       | I/O      | TTL         | GPIO port A bit 3.  |
|            | I2C8SDA   | I/O      | OD          | I <sup>2</sup> C module 8 data.   |
|            | SSI0Fss   | I/O      | TTL         | SSI module 0 frame signal   |
|            | T1CCP1    | I/O      | TTL         | 16/32-Bit Timer 1 Capture/Compare/PWM 1.  |
|            | U4Tx      | O        | TTL         | UART module 4 transmit.   |
| U6         | PF0       | I/O      | TTL         | GPIO port F bit 0.  |
|            | M0PWM0    | O        | TTL         | Motion Control Module 0 PWM 0. This signal is controlled by Module 0 PWM Generator 0.   |
|            | SSI3XDAT1 | I/O      | TTL         | SSI Module 3 Bi-directional Data Pin 1 (SSI3RX in Legacy SSI Mode).   |
|            | TRD2      | O        | TTL         | Trace data 2.   |
| U8         | PF7       | I/O      | TTL         | GPIO port F bit 7.  |

Table 28-2. Signals by Pin Number (continued)

| Pin Number | Pin Name  | Pin Type | Buffer Type | Description  |
|------------|-----------|----------|-------------|--|
| U10        | PS6       | I/O      | TTL         | GPIO port S bit 6.   |
|            | IDX0      | I        | TTL         | QEI module 0 index.  |
|            | T5CCP0    | I/O      | TTL         | 16/32-Bit Timer 5 Capture/Compare/PWM 0.   |
| U12        | PN7       | I/O      | TTL         | GPIO port N bit 7.   |
|            | U1RTS     | O        | TTL         | UART module 1 Request to Send modem flow control output line.  |
|            | U4CTS     | I        | TTL         | UART module 4 Clear To Send modem flow control input signal.   |
| U14        | PG7       | I/O      | TTL         | GPIO port G bit 7.   |
|            | I2C4SDA   | I/O      | OD          | I <sup>2</sup> C module 4 data.  |
|            | SSI2Clk   | I/O      | TTL         | SSI module 2 clock.  |
| U15        | PQ6       | I/O      | TTL         | GPIO port Q bit 6.   |
|            | U1DTR     | O        | TTL         | UART module 1 Data Terminal Ready modem status input signal.   |
| U18        | WAKE      | I        | TTL         | An external input that brings the processor out of Hibernate mode when asserted.   |
| U19        | PK4       | I/O      | TTL         | GPIO port K bit 4.   |
|            | EPI0S32   | I/O      | TTL         | EPI module 0 signal 32.  |
|            | I2C3SCL   | I/O      | OD          | I <sup>2</sup> C module 3 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
|            | M0PWM6    | O        | TTL         | Motion Control Module 0 PWM 6. This signal is controlled by Module 0 PWM Generator 3.  |
| V1         | GND       | -        | Power       | Ground reference for logic and I/O pins.   |
| V2         | PH7       | I/O      | TTL         | GPIO port H bit 7.   |
|            | U5Tx      | O        | TTL         | UART module 5 transmit.  |
|            | U7Tx      | O        | TTL         | UART module 7 transmit.  |
| V3         | PA0       | I/O      | TTL         | GPIO port A bit 0.   |
|            | CAN0Rx    | I        | TTL         | CAN module 0 receive.  |
|            | I2C9SCL   | I/O      | OD          | I <sup>2</sup> C module 9 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
|            | T0CCP0    | I/O      | TTL         | 16/32-Bit Timer 0 Capture/Compare/PWM 0.   |
|            | U0Rx      | I        | TTL         | UART module 0 receive.   |
| V4         | PA4       | I/O      | TTL         | GPIO port A bit 4.   |
|            | I2C7SCL   | I/O      | OD          | I <sup>2</sup> C module 7 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
|            | SSI0XDAT0 | I/O      | TTL         | SSI Module 0 Bi-directional Data Pin 0 (SSI0TX in Legacy SSI Mode).  |
|            | T2CCP0    | I/O      | TTL         | 16/32-Bit Timer 2 Capture/Compare/PWM 0.   |
|            | U3Rx      | I        | TTL         | UART module 3 receive.   |

Table 28-2. Signals by Pin Number (continued)

| Pin Number | Pin Name  | Pin Type | Buffer Type | Description  |
|------------|-----------|----------|-------------|--|
| V5         | PA6       | I/O      | TTL         | GPIO port A bit 6.   |
|            | EPI0S8    | I/O      | TTL         | EPI module 0 signal 8.   |
|            | I2C6SCL   | I/O      | OD          | I <sup>2</sup> C module 6 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
|            | SSI0XDAT2 | I/O      | TTL         | SSI Module 0 Bi-directional Data Pin 2.  |
|            | T3CCP0    | I/O      | TTL         | 16/32-Bit Timer 3 Capture/Compare/PWM 0.   |
|            | U2Rx      | I        | TTL         | UART module 2 receive.   |
|            | USB0EPEN  | O        | TTL         | Optionally used in Host mode to control an external power source to supply power to the USB bus.   |
| V6         | PF1       | I/O      | TTL         | GPIO port F bit 1.   |
|            | M0PWM1    | O        | TTL         | Motion Control Module 0 PWM 1. This signal is controlled by Module 0 PWM Generator 0.  |
|            | SSI3XDAT0 | I/O      | TTL         | SSI Module 3 Bi-directional Data Pin 0 (SSI3TX in Legacy SSI Mode).  |
|            | TRD1      | O        | TTL         | Trace data 1.  |
| V7         | PF4       | I/O      | TTL         | GPIO port F bit 4.   |
|            | M0FAULT0  | I        | TTL         | Motion Control Module 0 PWM Fault 0.   |
|            | SSI3XDAT2 | I/O      | TTL         | SSI Module 3 Bi-directional Data Pin 2.  |
|            | TRD3      | O        | TTL         | Trace data 3.  |
| V8         | PR3       | I/O      | TTL         | GPIO port R bit 3.   |
|            | I2C2SDA   | I/O      | OD          | I <sup>2</sup> C module 2 data.  |
|            | M0PWM3    | O        | TTL         | Motion Control Module 0 PWM 3. This signal is controlled by Module 0 PWM Generator 1.  |
| V9         | PS4       | I/O      | TTL         | GPIO port S bit 4.   |
|            | PhA0      | I        | TTL         | QEI module 0 phase A.  |
|            | T4CCP0    | I/O      | TTL         | 16/32-Bit Timer 4 Capture/Compare/PWM 0.   |
| V10        | PT1       | I/O      | TTL         | GPIO port T bit 1.   |
|            | CAN0Tx    | O        | TTL         | CAN module 0 transmit.   |
|            | T6CCP1    | I/O      | TTL         | 16/32-Bit Timer 6 Capture/Compare/PWM 1.   |
| V11        | PG2       | I/O      | TTL         | GPIO port G bit 2.   |
|            | I2C2SCL   | I/O      | OD          | I <sup>2</sup> C module 2 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
|            | SSI2XDAT3 | I/O      | TTL         | SSI Module 2 Bi-directional Data Pin 3.  |
| V12        | PG6       | I/O      | TTL         | GPIO port G bit 6.   |
|            | I2C4SCL   | I/O      | OD          | I <sup>2</sup> C module 4 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
|            | SSI2Fss   | I/O      | TTL         | SSI module 2 frame signal.   |
| V13        | NC        | -        | -           | No connect. Leave the pin electrically unconnected/isolated.   |
| V14        | NC        | -        | -           | No connect. Leave the pin electrically unconnected/isolated.   |
| V15        | NC        | -        | -           | No connect. Leave the pin electrically unconnected/isolated.   |

Table 28-2. Signals by Pin Number (continued)

| Pin Number | Pin Name  | Pin Type | Buffer Type | Description  |
|------------|-----------|----------|-------------|--|
| V16        | PK6       | I/O      | TTL         | GPIO port K bit 6.   |
|            | EPI0S25   | I/O      | TTL         | EPI module 0 signal 25.  |
|            | I2C4SCL   | I/O      | OD          | I <sup>2</sup> C module 4 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
|            | M0FAULT1  | I        | TTL         | Motion Control Module 0 PWM Fault 1.   |
| V17        | PK5       | I/O      | TTL         | GPIO port K bit 5.   |
|            | EPI0S31   | I/O      | TTL         | EPI module 0 signal 31.  |
|            | I2C3SDA   | I/O      | OD          | I <sup>2</sup> C module 3 data.  |
|            | M0PWM7    | O        | TTL         | Motion Control Module 0 PWM 7. This signal is controlled by Module 0 PWM Generator 3.  |
| V18        | NC        | -        | -           | No connect. Leave the pin electrically unconnected/isolated.   |
| V19        | NC        | -        | -           | No connect. Leave the pin electrically unconnected/isolated.   |
| W1         | GND       | -        | Power       | Ground reference for logic and I/O pins.   |
| W2         | GND       | -        | Power       | Ground reference for logic and I/O pins.   |
| W3         | PA1       | I/O      | TTL         | GPIO port A bit 1.   |
|            | CAN0Tx    | O        | TTL         | CAN module 0 transmit.   |
|            | I2C9SDA   | I/O      | OD          | I <sup>2</sup> C module 9 data.  |
|            | T0CCP1    | I/O      | TTL         | 16/32-Bit Timer 0 Capture/Compare/PWM 1.   |
|            | U0Tx      | O        | TTL         | UART module 0 transmit.  |
| W4         | PA5       | I/O      | TTL         | GPIO port A bit 5.   |
|            | I2C7SDA   | I/O      | OD          | I <sup>2</sup> C module 7 data.  |
|            | SSI0XDAT1 | I/O      | TTL         | SSI Module 0 Bi-directional Data Pin 1 (SSI0RX in Legacy SSI Mode).  |
|            | T2CCP1    | I/O      | TTL         | 16/32-Bit Timer 2 Capture/Compare/PWM 1.   |
|            | U3Tx      | O        | TTL         | UART module 3 transmit.  |
| W6         | PF2       | I/O      | TTL         | GPIO port F bit 2.   |
|            | M0PWM2    | O        | TTL         | Motion Control Module 0 PWM 2. This signal is controlled by Module 0 PWM Generator 1.  |
|            | SSI3Fss   | I/O      | TTL         | SSI module 3 frame signal.   |
|            | TRD0      | O        | TTL         | Trace data 0.  |
| W7         | PF5       | I/O      | TTL         | GPIO port F bit 5.   |
|            | SSI3XDAT3 | I/O      | TTL         | SSI Module 3 Bi-directional Data Pin 3.  |
| W9         | PR6       | I/O      | TTL         | GPIO port R bit 6.   |
|            | I2C4SCL   | I/O      | OD          | I <sup>2</sup> C module 4 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
|            | M0PWM6    | O        | TTL         | Motion Control Module 0 PWM 6. This signal is controlled by Module 0 PWM Generator 3.  |
|            | T1CCP0    | I/O      | TTL         | 16/32-Bit Timer 1 Capture/Compare/PWM 0.   |
|            | U1Tx      | O        | TTL         | UART module 1 transmit.  |
| W10        | PT0       | I/O      | TTL         | GPIO port T bit 0.   |
|            | CAN0Rx    | I        | TTL         | CAN module 0 receive.  |
|            | T6CCP0    | I/O      | TTL         | 16/32-Bit Timer 6 Capture/Compare/PWM 0.   |

Table 28-2. Signals by Pin Number (continued)

| Pin Number | Pin Name | Pin Type | Buffer Type | Description   |
|------------|----------|----------|-------------|---|
| W12        | PQ5      | I/O      | TTL         | GPIO port Q bit 5.  |
|            | U1Tx     | O        | TTL         | UART module 1 transmit.   |
| W13        | NC       | -        | -           | No connect. Leave the pin electrically unconnected/isolated.  |
| W15        | NC       | -        | -           | No connect. Leave the pin electrically unconnected/isolated.  |
| W16        | PK7      | I/O      | TTL         | GPIO port K bit 7.  |
|            | EPI0S24  | I/O      | TTL         | EPI module 0 signal 24.   |
|            | I2C4SDA  | I/O      | OD          | I <sup>2</sup> C module 4 data.   |
|            | MOFAULT2 | I        | TTL         | Motion Control Module 0 PWM Fault 2.  |
|            | RTCCLK   | O        | TTL         | Buffered version of the Hibernation module's 32.768-kHz clock. This signal is not output when the part is in Hibernate mode and before being configured after power-on reset. |
|            | U0RI     | I        | TTL         | UART module 0 Ring Indicator modem status input signal.   |
| W18        | NC       | -        | -           | No connect. Leave the pin electrically unconnected/isolated.  |
| W19        | NC       | -        | -           | No connect. Leave the pin electrically unconnected/isolated.  |

## 28.2 Signals by Signal Name

Table 28-3. Signals by Signal Name

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type | Description                           |
|----------|------------|--------------------------|----------|-------------|---------------------------------------|
| AIN0     | G2         | PE3                      | I        | Analog      | Analog-to-digital converter input 0.  |
| AIN1     | G1         | PE2                      | I        | Analog      | Analog-to-digital converter input 1.  |
| AIN2     | H2         | PE1                      | I        | Analog      | Analog-to-digital converter input 2.  |
| AIN3     | H3         | PE0                      | I        | Analog      | Analog-to-digital converter input 3.  |
| AIN4     | B2         | PD7                      | I        | Analog      | Analog-to-digital converter input 4.  |
| AIN5     | B3         | PD6                      | I        | Analog      | Analog-to-digital converter input 5.  |
| AIN6     | B4         | PD5                      | I        | Analog      | Analog-to-digital converter input 6.  |
| AIN7     | A4         | PD4                      | I        | Analog      | Analog-to-digital converter input 7.  |
| AIN8     | B5         | PE5                      | I        | Analog      | Analog-to-digital converter input 8.  |
| AIN9     | A5         | PE4                      | I        | Analog      | Analog-to-digital converter input 9.  |
| AIN10    | C6         | PB4                      | I        | Analog      | Analog-to-digital converter input 10. |
| AIN11    | B6         | PB5                      | I        | Analog      | Analog-to-digital converter input 11. |
| AIN12    | D1         | PD3                      | I        | Analog      | Analog-to-digital converter input 12. |
| AIN13    | D2         | PD2                      | I        | Analog      | Analog-to-digital converter input 13. |
| AIN14    | C1         | PD1                      | I        | Analog      | Analog-to-digital converter input 14. |
| AIN15    | C2         | PD0                      | I        | Analog      | Analog-to-digital converter input 15. |
| AIN16    | J1         | PK0                      | I        | Analog      | Analog-to-digital converter input 16. |
| AIN17    | J2         | PK1                      | I        | Analog      | Analog-to-digital converter input 17. |

| AIN20    | A7         | PE6                      | I        | Analog      | Analog-to-digital converter input 20. |
| AIN21    | B7         | PE7                      | I        | Analog      | Analog-to-digital converter input 21. |

Table 28-3. Signals by Signal Name (continued)

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type | Description   |
|----------|------------|--------------------------|----------|-------------|---|
| AIN22    | A8         | PP7                      | I        | Analog      | Analog-to-digital converter input 22.   |
| AIN23    | B8         | PP6                      | I        | Analog      | Analog-to-digital converter input 23.   |
| C0+      | L2         | PC6                      | I        | Analog      | Analog comparator 0 positive input.   |
| C0-      | K3         | PC7                      | I        | Analog      | Analog comparator 0 negative input.   |
| C0o      | C2<br>G18  | PD0 (5)<br>PL2 (5)       | O        | TTL         | Analog comparator 0 output.   |
| C1+      | M1         | PC5                      | I        | Analog      | Analog comparator 1 positive input.   |
| C1-      | M2         | PC4                      | I        | Analog      | Analog comparator 1 negative input.   |
| C1o      | C1<br>J18  | PD1 (5)<br>PL3 (5)       | O        | TTL         | Analog comparator 1 output.   |
| C2+      | D6         | PP0                      | I        | Analog      | Analog comparator 2 positive input.   |
| C2-      | D7         | PP1                      | I        | Analog      | Analog comparator 2 negative input.   |
| C2o      | D2         | PD2 (5)                  | O        | TTL         | Analog comparator 2 output.   |
| CAN0Rx   | V3<br>W10  | PA0 (7)<br>PT0 (7)       | I        | TTL         | CAN module 0 receive.   |
| CAN0Tx   | W3<br>V10  | PA1 (7)<br>PT1 (7)       | O        | TTL         | CAN module 0 transmit.  |
| CAN1Rx   | A16<br>E18 | PB0 (7)<br>PT2 (7)       | I        | TTL         | CAN module 1 receive.   |
| CAN1Tx   | B16<br>F17 | PB1 (7)<br>PT3 (7)       | O        | TTL         | CAN module 1 transmit.  |
| DIVSCLK  | A13        | PQ4 (7)                  | O        | TTL         | An optionally divided reference clock output based on a selected clock source. Note that this signal is not synchronized to the System Clock. |
| EPI0S0   | P4<br>J1   | PH0 (15)<br>PK0 (15)     | I/O      | TTL         | EPI module 0 signal 0.  |
| EPI0S1   | R2<br>J2   | PH1 (15)<br>PK1 (15)     | I/O      | TTL         | EPI module 0 signal 1.  |
| EPI0S2   | R1<br>K1   | PH2 (15)<br>PK2 (15)     | I/O      | TTL         | EPI module 0 signal 2.  |
| EPI0S3   | T1<br>K2   | PH3 (15)<br>PK3 (15)     | I/O      | TTL         | EPI module 0 signal 3.  |
| EPI0S4   | K3         | PC7 (15)                 | I/O      | TTL         | EPI module 0 signal 4.  |
| EPI0S5   | L2         | PC6 (15)                 | I/O      | TTL         | EPI module 0 signal 5.  |
| EPI0S6   | M1         | PC5 (15)                 | I/O      | TTL         | EPI module 0 signal 6.  |
| EPI0S7   | M2         | PC4 (15)                 | I/O      | TTL         | EPI module 0 signal 7.  |
| EPI0S8   | V5         | PA6 (15)                 | I/O      | TTL         | EPI module 0 signal 8.  |
| EPI0S9   | R7         | PA7 (15)                 | I/O      | TTL         | EPI module 0 signal 9.  |
| EPI0S10  | T14        | PG1 (15)                 | I/O      | TTL         | EPI module 0 signal 10.   |
| EPI0S11  | N15        | PG0 (15)                 | I/O      | TTL         | EPI module 0 signal 11.   |
| EPI0S12  | L19        | PM3 (15)                 | I/O      | TTL         | EPI module 0 signal 12.   |
| EPI0S13  | L18        | PM2 (15)                 | I/O      | TTL         | EPI module 0 signal 13.   |
| EPI0S14  | K19        | PM1 (15)                 | I/O      | TTL         | EPI module 0 signal 14.   |
| EPI0S15  | K18        | PM0 (15)                 | I/O      | TTL         | EPI module 0 signal 15.   |

Table 28-3. Signals by Signal Name (continued)

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type | Description             |
|----------|------------|--------------------------|----------|-------------|-------------------------|
| EPI0S16  | G16        | PL0 (15)                 | I/O      | TTL         | EPI module 0 signal 16. |
| EPI0S17  | H19        | PL1 (15)                 | I/O      | TTL         | EPI module 0 signal 17. |
| EPI0S18  | G18        | PL2 (15)                 | I/O      | TTL         | EPI module 0 signal 18. |
| EPI0S19  | J18        | PL3 (15)                 | I/O      | TTL         | EPI module 0 signal 19. |
| EPI0S20  | E3         | PQ0 (15)                 | I/O      | TTL         | EPI module 0 signal 20. |
| EPI0S21  | E2         | PQ1 (15)                 | I/O      | TTL         | EPI module 0 signal 21. |
| EPI0S22  | H4         | PQ2 (15)                 | I/O      | TTL         | EPI module 0 signal 22. |
| EPI0S23  | M4         | PQ3 (15)                 | I/O      | TTL         | EPI module 0 signal 23. |
| EPI0S24  | W16        | PK7 (15)                 | I/O      | TTL         | EPI module 0 signal 24. |
| EPI0S25  | V16        | PK6 (15)                 | I/O      | TTL         | EPI module 0 signal 25. |
| EPI0S26  | H18        | PL4 (15)                 | I/O      | TTL         | EPI module 0 signal 26. |
| EPI0S27  | A17        | PB2 (15)                 | I/O      | TTL         | EPI module 0 signal 27. |
| EPI0S28  | B17        | PB3 (15)                 | I/O      | TTL         | EPI module 0 signal 28. |
| EPI0S29  | A11<br>B13 | PN2 (15)<br>PP2 (15)     | I/O      | TTL         | EPI module 0 signal 29. |
| EPI0S30  | B10<br>C12 | PN3 (15)<br>PP3 (15)     | I/O      | TTL         | EPI module 0 signal 30. |
| EPI0S31  | V17        | PK5 (15)                 | I/O      | TTL         | EPI module 0 signal 31. |
| EPI0S32  | U19        | PK4 (15)                 | I/O      | TTL         | EPI module 0 signal 32. |
| EPI0S33  | G19        | PL5 (15)                 | I/O      | TTL         | EPI module 0 signal 33. |
| EPI0S34  | A10        | PN4 (15)                 | I/O      | TTL         | EPI module 0 signal 34. |
| EPI0S35  | B9         | PN5 (15)                 | I/O      | TTL         | EPI module 0 signal 35. |

Table 28-3. Signals by Signal Name (continued)

| Pin Name                | Pin Number   | Pin Mux / Pin Assignment | Pin Type | Buffer Type | Description  |
|-------------------------|--|--------------------------|----------|-------------|--|
| GND                     | F10<br>H10<br>H11<br>H12<br>J11<br>J12<br>K6<br>K9<br>P16<br>K10<br>R17<br>K13<br>K14<br>L8<br>L9<br>M8<br>M9<br>M10<br>N10<br>A1<br>A2<br>B1<br>V1<br>W1<br>W2<br>A18<br>A19<br>B19 | fixed                    | -        | Power       | Ground reference for logic and I/O pins.   |
| GND <sub>A</sub>        | G4   | fixed                    | -        | Power       | The ground reference for the analog circuits (ADC, Analog Comparators, etc.). These are separated from GND to minimize the electrical noise contained on V <sub>DD</sub> from affecting the analog functions.                                    |
| GND <sub>X</sub>        | R18  | fixed                    | -        | Power       | GND for the Hibernation oscillator. When using a crystal clock source, this pin should be connected to digital ground along with the crystal load capacitors. When using an external oscillator, this pin should be connected to digital ground. |
| GND <sub>X2</sub>       | D18  | fixed                    | -        | Power       | GND for the MOSC. When using a crystal clock source, this pin should be connected to digital ground along with the crystal load capacitors. When using an external oscillator, this pin should be connected to digital ground.                   |
| $\overline{\text{HTB}}$ | M17  | fixed                    | O        | TTL         | An output that indicates the processor is in Hibernate mode.   |
| I2C0SCL                 | A17  | PB2 (2)                  | I/O      | OD          | I <sup>2</sup> C module 0 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.   |
| I2C0SDA                 | B17  | PB3 (2)                  | I/O      | OD          | I <sup>2</sup> C module 0 data.  |
| I2C1SCL                 | N15<br>N5  | PG0 (2)<br>PR0 (2)       | I/O      | OD          | I <sup>2</sup> C module 1 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain.   |
| I2C1SDA                 | T14<br>N4  | PG1 (2)<br>PR1 (2)       | I/O      | OD          | I <sup>2</sup> C module 1 data.  |

Table 28-3. Signals by Signal Name (continued)

| Pin Name | Pin Number                    | Pin Mux / Pin Assignment                            | Pin Type | Buffer Type | Description  |

| PL7      | B18        | -                        | I/O      | TTL         | GPIO port L bit 7. |
| PM0      | K18        | -                        | I/O      | TTL         | GPIO port M bit 0. |
| PM1      | K19        | -                        | I/O      | TTL         | GPIO port M bit 1. |
| PM2      | L18        | -                        | I/O      | TTL         | GPIO port M bit 2. |
| PM3      | L19        | -                        | I/O      | TTL         | GPIO port M bit 3. |
| PM4      | M18        | -                        | I/O      | TTL         | GPIO port M bit 4. |
| PM5      | G15        | -                        | I/O      | TTL         | GPIO port M bit 5. |
| PM6      | N19        | -                        | I/O      | TTL         | GPIO port M bit 6. |
| PM7      | N18        | -                        | I/O      | TTL         | GPIO port M bit 7. |
| PN0      | C10        | -                        | I/O      | TTL         | GPIO port N bit 0. |
| PN1      | B11        | -                        | I/O      | TTL         | GPIO port N bit 1. |
| PN2      | A11        | -                        | I/O      | TTL         | GPIO port N bit 2. |
| PN3      | B10        | -                        | I/O      | TTL         | GPIO port N bit 3. |
| PN4      | A10        | -                        | I/O      | TTL         | GPIO port N bit 4. |
| PN5      | B9         | -                        | I/O      | TTL         | GPIO port N bit 5. |
| PN6      | T12        | -                        | I/O      | TTL         | GPIO port N bit 6. |
| PN7      | U12        | -                        | I/O      | TTL         | GPIO port N bit 7. |
| PP0      | D6         | -                        | I/O      | TTL         | GPIO port P bit 0. |
| PP1      | D7         | -                        | I/O      | TTL         | GPIO port P bit 1. |
| PP2      | B13        | -                        | I/O      | TTL         | GPIO port P bit 2. |
| PP3      | C12        | -                        | I/O      | TTL         | GPIO port P bit 3. |
| PP4      | D8         | -                        | I/O      | TTL         | GPIO port P bit 4. |
| PP5      | B12        | -                        | I/O      | TTL         | GPIO port P bit 5. |
| PP6      | B8         | -                        | I/O      | TTL         | GPIO port P bit 6. |
| PP7      | A8         | -                        | I/O      | TTL         | GPIO port P bit 7. |
| PQ0      | E3         | -                        | I/O      | TTL         | GPIO port Q bit 0. |
| PQ1      | E2         | -                        | I/O      | TTL         | GPIO port Q bit 1. |
| PQ2      | H4         | -                        | I/O      | TTL         | GPIO port Q bit 2. |
| PQ3      | M4         | -                        | I/O      | TTL         | GPIO port Q bit 3. |
| PQ4      | A13        | -                        | I/O      | TTL         | GPIO port Q bit 4. |
| PQ5      | W12        | -                        | I/O      | TTL         | GPIO port Q bit 5. |
| PQ6      | U15        | -                        | I/O      | TTL         | GPIO port Q bit 6. |
| PQ7      | M3         | -                        | I/O      | TTL         | GPIO port Q bit 7. |
| PR0      | N5         | -                        | I/O      | TTL         | GPIO port R bit 0. |
| PR1      | N4         | -                        | I/O      | TTL         | GPIO port R bit 1. |
| PR2      | N2         | -                        | I/O      | TTL         | GPIO port R bit 2. |
| PR3      | V8         | -                        | I/O      | TTL         | GPIO port R bit 3. |
| PR4      | P3         | -                        | I/O      | TTL         | GPIO port R bit 4. |
| PR5      | P2         | -                        | I/O      | TTL         | GPIO port R bit 5. |
| PR6      | W9         | -                        | I/O      | TTL         | GPIO port R bit 6. |
| PR7      | R10        | -                        | I/O      | TTL         | GPIO port R bit 7. |

Table 28-3. Signals by Signal Name (continued)

| Pin Name                | Pin Number       | Pin Mux / Pin Assignment      | Pin Type | Buffer Type | Description   |
|-------------------------|------------------|-------------------------------|----------|-------------|---|
| PS0                     | D12              | -                             | I/O      | TTL         | GPIO port S bit 0.  |
| PS1                     | D13              | -                             | I/O      | TTL         | GPIO port S bit 1.  |
| PS2                     | B14              | -                             | I/O      | TTL         | GPIO port S bit 2.  |
| PS3                     | A14              | -                             | I/O      | TTL         | GPIO port S bit 3.  |
| PS4                     | V9               | -                             | I/O      | TTL         | GPIO port S bit 4.  |
| PS5                     | T13              | -                             | I/O      | TTL         | GPIO port S bit 5.  |
| PS6                     | U10              | -                             | I/O      | TTL         | GPIO port S bit 6.  |

| USB0DIR  | C12             | PP3 (14)                       | O        | TTL         | Indicates that the external PHY is able to accept data from the USB controller.                  |
| USB0DM   | B18             | PL7                            | I/O      | Analog      | Bidirectional differential data pin (D- per USB specification) for USB0.                         |
| USB0DP   | C18             | PL6                            | I/O      | Analog      | Bidirectional differential data pin (D+ per USB specification) for USB0.                         |
| USB0EPEN | V5<br>R7<br>B3  | PA6 (5)<br>PA7 (11)<br>PD6 (5) | O        | TTL         | Optionally used in Host mode to control an external power source to supply power to the USB bus. |

Table 28-3. Signals by Signal Name (continued)

| Pin Name | Pin Number   | Pin Mux / Pin Assignment | Pin Type | Buffer Type | Description   |
|----------|--|--------------------------|----------|-------------|---|
| USB0ID   | A16  | PB0                      | I        | Analog      | This signal senses the state of the USB ID signal. The USB PHY enables an integrated pull-up, and an external element (USB connector) indicates the initial state of the USB controller (pulled down is the A side of the cable and pulled up is the B side).   |
| USB0NXT  | B13  | PP2 (14)                 | O        | TTL         | Asserted by the external PHY to throttle all data types.  |
| USB0PFLT | R7<br>B2   | PA7 (5)<br>PD7 (5)       | I        | TTL         | Optionally used in Host mode by an external power source to indicate an error state by that power source.   |
| USB0STP  | A17  | PB2 (14)                 | O        | TTL         | Asserted by the USB controller to signal the end of a USB transmit packet or register write operation.  |
| USB0VBUS | B16  | PB1                      | I/O      | Analog      | This signal is used during the session request protocol. This signal allows the USB PHY to both sense the voltage level of VBUS, and pull up VBUS momentarily during VBUS pulsing.  |
| VBAT     | P19  | fixed                    | -        | Power       | Power source for the Hibernation module. It is normally connected to the positive terminal of a battery and serves as the battery backup/Hibernation module power-source supply.  |
| VDD      | G10<br>H9<br>J8<br>J9<br>J10<br>K7<br>K8<br>K11<br>N16<br>P17<br>K12<br>L10<br>L11<br>L12<br>M11<br>M12<br>P10 | fixed                    | -        | Power       | Positive supply for I/O and some logic.   |
| VDDA     | F3   | fixed                    | -        | Power       | The positive supply for the analog circuits (ADC, Analog Comparators, etc.). These are separated from VDD to minimize the electrical noise contained on VDD from affecting the analog functions. VDDA pins must be supplied with a voltage that meets the specification in , regardless of system implementation. |
| VDDC     | H16<br>E10   | fixed                    | -        | Power       | Positive supply for most of the logic function, including the processor core and most peripherals. The voltage on this pin is 1.2 V and is supplied by the on-chip LDO. The VDDC pins should only be connected to each other and an external capacitor as specified in Table 29-15 on page 1721 .                 |

Table 28-3. Signals by Signal Name (continued)

| Pin Name | Pin Number | Pin Mux / Pin Assignment | Pin Type | Buffer Type | Description  |
|----------|------------|--------------------------|----------|-------------|--|
| VREFA+   | F4         | fixed                    | -        | Analog      | A reference voltage used to specify the voltage at which the ADC converts to a maximum value. This pin is used in conjunction with VREFA-, which specifies the minimum value. The voltage that is applied to VREFA+ is the voltage with which an AIN <sub>n</sub> signal is converted to 4095. The VREFA+ voltage is limited to the range specified in Table 29-44 on page 1748.   |
| VREFA-   | G5         | fixed                    | -        | Analog      | A reference voltage used to specify the input voltage at which the ADC converts to a minimum value. This pin is used in conjunction with VREFA+, which specifies the maximum value. In other words, the voltage that is applied to VREFA- is the voltage with which an AIN <sub>n</sub> signal is converted to 0, while the voltage that is applied to VREFA+ is the voltage with which an AIN <sub>n</sub> signal is converted to 4095. The VREFA- voltage is limited to the range specified in Table 29-44 on page 1748. |
| WAKE     | U18        | fixed                    | I        | TTL         | An external input that brings the processor out of Hibernate mode when asserted.   |
| XOSC0    | T18        | fixed                    | I        | Analog      | Hibernation module oscillator crystal input or an external clock reference input. Note that this is either a crystal or a 32.768-kHz oscillator for the Hibernation module RTC.  |
| XOSC1    | T19        | fixed                    | O        | Analog      | Hibernation module oscillator crystal output. Leave unconnected when using a single-ended clock source.  |

## 28.3 Signals by Function, Except for GPIO

Table 28-4. Signals by Function, Except for GPIO

| Function | Pin Name | Pin Number | Pin Type | Buffer Type | Description  |
|----------|----------|------------|----------|-------------|--|
| ADC      | AIN0     | G2         | I        | Analog      | Analog-to-digital converter input 0.   |
|          | AIN1     | G1         | I        | Analog      | Analog-to-digital converter input 1.   |
|          | AIN2     | H2         | I        | Analog      | Analog-to-digital converter input 2.   |
|          | AIN3     | H3         | I        | Analog      | Analog-to-digital converter input 3.   |
|          | AIN4     | B2         | I        | Analog      | Analog-to-digital converter input 4.   |
|          | AIN5     | B3         | I        | Analog      | Analog-to-digital converter input 5.   |
|          | AIN6     | B4         | I        | Analog      | Analog-to-digital converter input 6.   |
|          | AIN7     | A4         | I        | Analog      | Analog-to-digital converter input 7.   |
|          | AIN8     | B5         | I        | Analog      | Analog-to-digital converter input 8.   |
|          | AIN9     | A5         | I        | Analog      | Analog-to-digital converter input 9.   |
|          | AIN10    | C6         | I        | Analog      | Analog-to-digital converter input 10.  |
|          | AIN11    | B6         | I        | Analog      | Analog-to-digital converter input 11.  |
|          | AIN12    | D1         | I        | Analog      | Analog-to-digital converter input 12.  |
|          | AIN13    | D2         | I        | Analog      | Analog-to-digital converter input 13.  |
|          | AIN14    | C1         | I        | Analog      | Analog-to-digital converter input 14.  |
|          | AIN15    | C2         | I        | Analog      | Analog-to-digital converter input 15.  |
|          | AIN16    | J1         | I        | Analog      | Analog-to-digital converter input 16.  |
|          | AIN17    | J2         | I        | Analog      | Analog-to-digital converter input 17.  |
|          | AIN18    | K1         | I        | Analog      | Analog-to-digital converter input 18.  |
|          | AIN19    | K2         | I        | Analog      | Analog-to-digital converter input 19.  |
|          | AIN20    | A7         | I        | Analog      | Analog-to-digital converter input 20.  |
|          | AIN21    | B7         | I        | Analog      | Analog-to-digital converter input 21.  |
|          | AIN22    | A8         | I        | Analog      | Analog-to-digital converter input 22.  |
|          | AIN23    | B8         | I        | Analog      | Analog-to-digital converter input 23.  |
|          | VREFA+   | F4         | -        | Analog      | A reference voltage used to specify the voltage at which the ADC converts to a maximum value. This pin is used in conjunction with VREFA-, which specifies the minimum value. The voltage that is applied to VREFA+ is the voltage with which an AINn signal is converted to 4095. The VREFA+ voltage is limited to the range specified in Table 29-44 on page 1748.   |
|          | VREFA-   | G5         | -        | Analog      | A reference voltage used to specify the input voltage at which the ADC converts to a minimum value. This pin is used in conjunction with VREFA+, which specifies the maximum value. In other words, the voltage that is applied to VREFA- is the voltage with which an AINn signal is converted to 0, while the voltage that is applied to VREFA+ is the voltage with which an AINn signal is converted to 4095. The VREFA- voltage is limited to the range specified in Table 29-44 on page 1748. |

Table 28-4. Signals by Function, Except for GPIO (continued)

| Function                | Pin Name | Pin Number | Pin Type | Buffer Type | Description                         |
|-------------------------|----------|------------|----------|-------------|-------------------------------------|
| Analog Comparators      | C0+      | L2         | I        | Analog      | Analog comparator 0 positive input. |
|                         | C0-      | K3         | I        | Analog      | Analog comparator 0 negative input. |
|                         | C0o      | C2<br>G18  | O        | TTL         | Analog comparator 0 output.         |
|                         | C1+      | M1         | I        | Analog      | Analog comparator 1 positive input. |
|                         | C1-      | M2         | I        | Analog      | Analog comparator 1 negative input. |
|                         | C1o      | C1<br>J18  | O        | TTL         | Analog comparator 1 output.         |
|                         | C2+      | D6         | I        | Analog      | Analog comparator 2 positive input. |
|                         | C2-      | D7         | I        | Analog      | Analog comparator 2 negative input. |
|                         | C2o      | D2         | O        | TTL         | Analog comparator 2 output.         |
| Controller Area Network | CAN0Rx   | V3<br>W10  | I        | TTL         | CAN module 0 receive.               |
|                         | CAN0Tx   | W3<br>V10  | O        | TTL         | CAN module 0 transmit.              |
|                         | CAN1Rx   | A16<br>E18 | I        | TTL         | CAN module 1 receive.               |
|                         | CAN1Tx   | B16<br>F17 | O        | TTL         | CAN module 1 transmit.              |
| Core                    | TRCLK    | T7         | O        | TTL         | Trace clock.                        |
|                         | TRD0     | W6         | O        | TTL         | Trace data 0.                       |
|                         | TRD1     | V6         | O        | TTL         | Trace data 1.                       |
|                         | TRD2     | U6         | O        | TTL         | Trace data 2.                       |
|                         | TRD3     | V7         | O        | TTL         | Trace data 3.                       |

Table 28-4. Signals by Function, Except for GPIO (continued)

| Function                      | Pin Name | Pin Number | Pin Type | Buffer Type             | Description             |
|-------------------------------|----------|------------|----------|-------------------------|-------------------------|
| External Peripheral Interface | EPI0S0   | P4<br>J1   | I/O      | TTL                     | EPI module 0 signal 0.  |

Table 28-4. Signals by Function, Except for GPIO (continued)

| Function  | Pin Name | Pin Number       | Pin Type | Buffer Type   | Description  |
|-----------|----------|------------------|----------|---|--|
|           |          | M2<br>H4<br>E18  |          |   |  |
|           | T7CCP1   | M1<br>M4<br>F17  | I/O      | TTL   | 16/32-Bit Timer 7 Capture/Compare/PWM 1.   |
| Hibernate | GNDX     | R18              | -        | Power   | GND for the Hibernation oscillator. When using a crystal clock source, this pin should be connected to digital ground along with the crystal load capacitors. When using an external oscillator, this pin should be connected to digital ground. |
|           | HTB      | M17              | O        | TTL   | An output that indicates the processor is in Hibernate mode.   |
|           | RTCCLK   | M1<br>W16<br>C12 | O        | TTL   | Buffered version of the Hibernation module's 32.768-kHz clock. This signal is not output when the part is in Hibernate mode and before being configured after power-on reset.  |
|           | TMPR0    | N18              | I/O      | TTL   | Tamper signal 0.   |
|           | TMPR1    | N19              | I/O      | TTL   | Tamper signal 1.   |
|           | TMPR2    | G15              | I/O      | TTL   | Tamper signal 2.   |
|           | TMPR3    | M18              | I/O      | TTL   | Tamper signal 3.   |
|           | VBAT     | P19              | -        | Power   | Power source for the Hibernation module. It is normally connected to the positive terminal of a battery and serves as the battery backup/Hibernation module power-source supply.   |
|           | WAKE     | U18              | I        | TTL   | An external input that brings the processor out of Hibernate mode when asserted.   |
|           | XOSC0    | T18              | I        | Analog  | Hibernation module oscillator crystal input or an external clock reference input. Note that this is either a crystal or a 32.768-kHz oscillator for the Hibernation module RTC.  |
| XOSC1     | T19      | O                | Analog   | Hibernation module oscillator crystal output. Leave unconnected when using a single-ended clock source. |  |

Table 28-4. Signals by Function, Except for GPIO (continued)

| Function | Pin Name | Pin Number                    | Pin Type | Buffer Type | Description  |
|----------|----------|-------------------------------|----------|-------------|--|
| I2C      | I2C0SCL  | A17                           | I/O      | OD          | I <sup>2</sup> C module 0 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
|          | I2C0SDA  | B17                           | I/O      | OD          | I <sup>2</sup> C module 0 data.  |
|          | I2C1SCL  | N15<br>N5                     | I/O      | OD          | I <sup>2</sup> C module 1 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
|          | I2C1SDA  | T14<br>N4                     | I/O      | OD          | I <sup>2</sup> C module 1 data.  |
|          | I2C2SCL  | V11<br>H19<br>B9<br>B12<br>N2 | I/O      | OD          | I <sup>2</sup> C module 2 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
|          | I2C2SDA  | M16<br>G16<br>A10<br>B8<br>V8 | I/O      | OD          | I <sup>2</sup> C module 2 data.  |
|          | I2C3SCL  | K17<br>U19<br>P3              | I/O      | OD          | I <sup>2</sup> C module 3 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
|          | I2C3SDA  | K15<br>V17<br>P2              | I/O      | OD          | I <sup>2</sup> C module 3 data.  |
|          | I2C4SCL  | V12<br>V16<br>W9              | I/O      | OD          | I <sup>2</sup> C module 4 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
|          | I2C4SDA  | U14<br>W16<br>R10             | I/O      | OD          | I <sup>2</sup> C module 4 data.  |
|          | I2C5SCL  | A16<br>C6                     | I/O      | OD          | I <sup>2</sup> C module 5 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
|          | I2C5SDA  | B16<br>B6                     | I/O      | OD          | I <sup>2</sup> C module 5 data.  |
|          | I2C6SCL  | V5<br>F2                      | I/O      | OD          | I <sup>2</sup> C module 6 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
|          | I2C6SDA  | R7<br>F1                      | I/O      | OD          | I <sup>2</sup> C module 6 data.  |
|          | I2C7SCL  | V4<br>C2                      | I/O      | OD          | I <sup>2</sup> C module 7 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
|          | I2C7SDA  | W4<br>C1                      | I/O      | OD          | I <sup>2</sup> C module 7 data.  |
|          | I2C8SCL  | T6<br>D2                      | I/O      | OD          | I <sup>2</sup> C module 8 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
|          | I2C8SDA  | U5<br>D1                      | I/O      | OD          | I <sup>2</sup> C module 8 data.  |

Table 28-4. Signals by Function, Except for GPIO (continued)

| Function     | Pin Name | Pin Number | Pin Type | Buffer Type | Description  |
|--------------|----------|------------|----------|-------------|--|
|              | I2C9SCL  | V3<br>A7   | I/O      | OD          | I <sup>2</sup> C module 9 clock. Note that this signal has an active pull-up. The corresponding port pin should not be configured as open drain. |
|              | I2C9SDA  | W3<br>B7   | I/O      | OD          | I <sup>2</sup> C module 9 data.  |
| JTAG/SWD/SWO | SWCLK    | B15        | I        | TTL         | JTAG/SWD CLK.  |
|              | SWDIO    | C15        | I/O      | TTL         | JTAG TMS and SWDIO.  |
|              | SWO      | C14        | O        | TTL         | JTAG TDO and SWO.  |
|              | TCK      | B15        | I        | TTL         | JTAG/SWD CLK.  |
|              | TDI      | D14        | I        | TTL         | JTAG TDI.  |
|              | TDO      | C14        | O        | TTL         | JTAG TDO and SWO.  |
|              | TMS      | C15        | I        | TTL         | JTAG TMS and SWDIO.  |
| PWM          | M0FAULT0 | V7<br>D12  | I        | TTL         | Motion Control Module 0 PWM Fault 0.   |
|              | M0FAULT1 | V16<br>D13 | I        | TTL         | Motion Control Module 0 PWM Fault 1.   |
|              | M0FAULT2 | W16<br>B14 | I        | TTL         | Motion Control Module 0 PWM Fault 2.   |
|              | M0FAULT3 | G16<br>A14 | I        | TTL         | Motion Control Module 0 PWM Fault 3.   |
|              | M0PWM0   | U6<br>N5   | O        | TTL         | Motion Control Module 0 PWM 0. This signal is controlled by Module 0 PWM Generator 0.  |
|              | M0PWM1   | V6<br>N4   | O        | TTL         | Motion Control Module 0 PWM 1. This signal is controlled by Module 0 PWM Generator 0.  |
|              | M0PWM2   | W6<br>N2   | O        | TTL         | Motion Control Module 0 PWM 2. This signal is controlled by Module 0 PWM Generator 1.  |
|              | M0PWM3   | T7<br>V8   | O        | TTL         | Motion Control Module 0 PWM 3. This signal is controlled by Module 0 PWM Generator 1.  |
|              | M0PWM4   | N15<br>P3  | O        | TTL         | Motion Control Module 0 PWM 4. This signal is controlled by Module 0 PWM Generator 2.  |
|              | M0PWM5   | T14<br>P2  | O        | TTL         | Motion Control Module 0 PWM 5. This signal is controlled by Module 0 PWM Generator 2.  |
|              | M0PWM6   | U19<br>W9  | O        | TTL         | Motion Control Module 0 PWM 6. This signal is controlled by Module 0 PWM Generator 3.  |
|              | M0PWM7   | V17<br>R10 | O        | TTL         | Motion Control Module 0 PWM 7. This signal is controlled by Module 0 PWM Generator 3.  |

Table 28-4. Signals by Function, Except for GPIO (continued)

| Function | Pin Name | Pin Number | Pin Type | Buffer Type | Description   |   |       |   |
|----------|----------|------------|----------|-------------|---|---|-------|---|
| Power    | GND      | F10        | -        | Power       | Ground reference for logic and I/O pins.  |   |       |   |
|          |          | H10        |          |             |   |   |       |   |
|          |          | H11        |          |             |   |   |       |   |
|          |          | H12        |          |             |   |   |       |   |
|          |          | J11        |          |             |   |   |       |   |
| Power    | GND      | J12        |          | Power       | Ground reference for logic and I/O pins.  |   |       |   |
|          |          | K6         |          |             |   |   |       |   |
|          |          | K9         |          |             |   |   |       |   |
|          |          | P16        |          |             |   |   |       |   |
|          |          | K10        |          |             |   |   |       |   |
|          |          | R17        |          |             |   |   |       |   |
|          |          | K13        |          |             |   |   |       |   |
|          |          | K14        |          |             |   |   |       |   |
|          |          | L8         |          |             |   |   |       |   |
|          |          | L9         |          |             |   |   |       |   |
|          |          | M8         |          |             |   |   |       |   |
|          |          | M9         |          |             |   |   |       |   |
|          |          | M10        |          |             |   |   |       |   |
|          |          | N10        |          |             |   |   |       |   |
|          |          | A1         |          |             |   |   |       |   |
|          |          | A2         |          |             |   |   |       |   |
|          |          | B1         |          |             |   |   |       |   |
|          |          | V1         |          |             |   |   |       |   |
|          |          | W1         |          |             |   |   |       |   |
|          |          | W2         |          |             |   |   |       |   |
| A18      |          |            |          |             |   |   |       |   |
| A19      |          |            |          |             |   |   |       |   |
| B19      |          |            |          |             |   |   |       |   |
| Power    | GNDA     | G4         | -        | Power       | The ground reference for the analog circuits (ADC, Analog Comparators, etc.). These are separated from GND to minimize the electrical noise contained on VDD from affecting the analog functions.   |   |       |   |
|          |          | VDD        | G10      |             |   | - | Power | Positive supply for I/O and some logic. |
|          |          |            | H9       |             |   |   |       |   |
|          |          |            | J8       |             |   |   |       |   |
|          |          |            | J9       |             |   |   |       |   |
| J10      |          |            |          |             |   |   |       |   |
| Power    | VDD      | K7         |          | Power       | Positive supply for I/O and some logic.   |   |       |   |

|          | USB0D6   | B12            | I/O      | TTL  | USB data 6.   |
|          | USB0D7   | D8             | I/O      | TTL  | USB data 7.   |
|          | USB0DIR  | C12            | O        | TTL  | Indicates that the external PHY is able to accept data from the USB controller.   |
|          | USB0DM   | B18            | I/O      | Analog   | Bidirectional differential data pin (D- per USB specification) for USB0.  |
|          | USB0DP   | C18            | I/O      | Analog   | Bidirectional differential data pin (D+ per USB specification) for USB0.  |
|          | USB0EPEN | V5<br>R7<br>B3 | O        | TTL  | Optionally used in Host mode to control an external power source to supply power to the USB bus.  |
|          | USB0ID   | A16            | I        | Analog   | This signal senses the state of the USB ID signal. The USB PHY enables an integrated pull-up, and an external element (USB connector) indicates the initial state of the USB controller (pulled down is the A side of the cable and pulled up is the B side). |
|          | USB0NXT  | B13            | O        | TTL  | Asserted by the external PHY to throttle all data types.  |
|          | USB0PFLT | R7<br>B2       | I        | TTL  | Optionally used in Host mode by an external power source to indicate an error state by that power source.   |
| USB0STP  | A17      | O              | TTL      | Asserted by the USB controller to signal the end of a USB transmit packet or register write operation.   |   |
| USB0VBUS | B16      | I/O            | Analog   | This signal is used during the session request protocol. This signal allows the USB PHY to both sense the voltage level of VBUS, and pull up VBUS momentarily during VBUS pulsing. |   |

## 28.4 GPIO Pins and Alternate Functions

Table 28-5. GPIO Pins and Alternate Functions

| IO  | Pin | Analog or Special Function <sup>a</sup> | Digital Function (GPIOCTL PMCx Bit Field Encoding) <sup>b</sup> |         |        |   |   |   |        |   |    |    |    |          |

a. The TMPRn signals are digital signals enabled and configured by the Hibernation module. All other signals listed in this column are analog signals.

b. The digital signals that are shaded gray are the power-on default values for the corresponding GPIO pin. Encodings 9, 10, and 12 are not used on this device.

## 28.5 Possible Pin Assignments for Alternate Functions

Table 28-6. Possible Pin Assignments for Alternate Functions

| # of Possible Assignments | Alternate Function | GPIO Function |
|---------------------------|--------------------|---------------|
| one                       | AIN0               | PE3           |
|                           | AIN1               | PE2           |
|                           | AIN10              | PB4           |
|                           | AIN11              | PB5           |
|                           | AIN12              | PD3           |
|                           | AIN13              | PD2           |
|                           | AIN14              | PD1           |

## 28.6 Connections for Unused Signals

Table 28-7 on page 1704 show how to handle signals for functions that are not used in a particular system implementation for devices that are in a 212-ball BGA package. Two options are shown in the table: an acceptable practice and a preferred practice for reduced power consumption and improved EMC characteristics. If a module is not used in a system, and its inputs are grounded, it is important that the clock to the module is never enabled by setting the corresponding bit in the **RCGCx** register.

Table 28-7. Connections for Unused Signals (212-Ball BGA)

| Function       | Signal Name      | Pin Number                                    | Acceptable Practice | Preferred Practice                             |
|----------------|------------------|---|---------------------|--|
| ADC            | VREFA+           | F4  | VDDA                | VDDA   |
|                | VREFA-           | G5  | GND                 | GND  |
| GPIO           | PA1(UART0TX)     | W3  | NC                  | GND <sup>a</sup>                               |
|                | PA4 (SSIOXDAT0)  | V4  | NC                  | GND <sup>b</sup>                               |
|                | All unused GPIOs | -   | NC                  | GND  |
| Hibernate      | GNDX             | R18   | GND                 | GND  |
|                | HTB              | M17   | NC                  | NC   |
|                | VBAT             | P19   | NC                  | VDD  |
|                | WAKE             | U18   | NC                  | GND  |
|                | XOSC0            | T18   | NC                  | GND  |
|                | XOSC1            | T19   | NC                  | NC   |
| No Connects    | NC               | See NC pin numbers in Table 28-3 on page 1664 | NC                  | NC   |
| System Control | GNDX2            | D18   | GND                 | GND  |
|                | OSC0             | E19   | NC                  | GND  |
|                | OSC1             | D19   | NC                  | NC   |
|                | RST              | P18   | VDD                 | Pull up as shown in Figure 5-1 on page 226     |
| USB            | USB0DM / PL7     | B18   | NC                  | Pull-down to GND with 1K resistor <sup>c</sup> |
|                | USB0DP / PL6     | C18   | NC                  | Pull-down to GND with 1K resistor <sup>c</sup> |

a. PA1 (UART0TX) may be enabled as an output by the ROM boot loader if no code is present in the flash and PA0 (UART0RX) receives a valid boot signature. Ensure that this condition will not occur if PA1 is to be connected directly to GND.

b. PA4 (SSIOXDAT0) may be enabled as an output by the ROM boot loader if no code is present in the flash and the SSIOX (PA2, PA3, PA5) receives a valid boot signature. Ensure that this condition will not occur if PA4 is to be connected directly to GND.

c. The ROM boot loader may configure these pins as USB pins if no code is present in the flash therefore they should not be directly connected to ground.

## 29 Electrical Characteristics

### 29.1 Maximum Ratings

The maximum ratings are the limits to which the device can be subjected without permanently damaging the device. Device reliability may be adversely affected by exposure to absolute-maximum ratings for extended periods.

**Note:** The device is not guaranteed to operate properly at the maximum ratings.

**Table 29-1. Absolute Maximum Ratings**

| Parameter             | Parameter Name <sup>a</sup>                       | Value |     | Unit |
|-----------------------|---|-------|-----|------|
|                       |   | Min   | Max |      |
| V <sub>DD</sub>       | V <sub>DD</sub> supply voltage                    | 0     | 4   | V    |
| V <sub>DDA</sub>      | V <sub>DDA</sub> supply voltage                   | 0     | 4   | V    |
| V <sub>BAT</sub>      | V <sub>BAT</sub> battery supply voltage           | 0     | 4   | V    |
| V <sub>BATRMP</sub>   | V <sub>BAT</sub> battery supply voltage ramp time | 0     | 0.7 | V/μs |
| V <sub>IN_GPIO</sub>  | Input voltage <sup>b</sup>                        | -0.3  | 4   | V    |
| I <sub>GPIO MAX</sub> | Maximum current per output pin                    | -     | 64  | mA   |
| T <sub>S</sub>        | Unpowered storage temperature range               | -65   | 150 | °C   |
| T <sub>JMAX</sub>     | Maximum junction temperature                      | -     | 125 | °C   |

a. Voltages are measured with respect to GND.

b. Applies to static and dynamic signals including overshoot.

**Important:** This device contains circuitry to protect the I/Os against damage due to high-static voltages; however, it is advised that normal precautions be taken to avoid application of any voltage higher than maximum-rated voltages to this high-impedance circuit. Reliability of operation is enhanced if unused inputs are connected to an appropriate logic voltage level (see “Connections for Unused Signals” on page 1704).

**Table 29-2. ESD Absolute Maximum Ratings**

| Parameter                                       | Parameter Name                   | Min | Nom | Max | Unit |
|---|----------------------------------|-----|-----|-----|------|
| Component-Level ESD Stress Voltage <sup>a</sup> | V <sub>ESDHBM</sub> <sup>b</sup> | -   | -   | 2.0 | kV   |
|   | V <sub>ESDCDM</sub> <sup>c</sup> | -   | -   | 500 | V    |

a. Electrostatic discharge (ESD) is used to measure device sensitivity/immunity to damage caused by electrostatic discharges in device.

b. All pins are HBM compliant to 2 kV for all combinations as per JESD22-A114F, except for the following stress combinations:

- The GPIO pins PM4, PM5, PM6, and PM7 to other pins.

These exceptions are compliant to 500 V and do not require any special handling beyond typical ESD control procedures during assembly operations per JEDEC publication JEP155. Note that these pins do meet the 500 V CDM specification.

c. Level listed is the passing level per EIA-JEDEC JESD22-C101E. JEDEC document JEP157 states that 250 V CDM allows safe manufacturing with a standard ESD control process.

## 29.2 Operating Characteristics

**Table 29-3. Temperature Characteristics**

| Characteristic                       | Symbol | Value  | Unit |
|--------------------------------------|--------|--|------|
| Ambient operating temperature range  | $T_A$  | -40 to 85 (industrial temperature part)<br>-40 to 105 (extended temperature part)  | °C   |
| Junction operating temperature range | $T_J$  | -40 to 105 (industrial temperature part)<br>-40 to 125 (extended temperature part) | °C   |

**Table 29-4. 212 BGA Power Dissipation<sup>ab</sup>**

| Parameter | Parameter Name                                  | $T_A$                               | $T_J$                                | Min | Max  | Unit |
|-----------|---|-------------------------------------|--------------------------------------|-----|------|------|
| $P_{DI}$  | Industrial temperature device power dissipation | 85 °C (industrial temperature part) | 125 °C (industrial temperature part) | -   | 1018 | mW   |
| $P_{DE}$  | Extended temperature device power dissipation   | 105 °C (extended temperature part)  | 125 °C (extended temperature part)   | -   | 509  | mW   |

- a. If the device exceeds the power dissipation value shown, then modifications such as heat sinks or fans must be used to conform to the limits shown.
- b. A larger power dissipation allowance can be achieved by lowering  $T_A$  as long as  $T_{JMAX}$  shown in Table 29-1 on page 1705 is not exceeded.

**Table 29-5. Thermal Characteristics<sup>a</sup>**

| Characteristic  | Symbol        | Value   | Unit |
|---|---------------|---|------|
| Thermal resistance (junction to ambient) <sup>b</sup> | $\Theta_{JA}$ | 39.3  | °C/W |
| Thermal resistance (junction to board) <sup>b</sup>   | $\Theta_{JB}$ | 18.6  | °C/W |
| Thermal resistance (junction to case) <sup>b</sup>    | $\Theta_{JC}$ | 12.9  | °C/W |
| Thermal metric (junction to top of package)           | $\Psi_{JT}$   | 0.2   | °C/W |
| Thermal metric (junction to board)                    | $\Psi_{JB}$   | 18.4  | °C/W |
| Junction temperature formula                          | $T_J$         | $T_C + (P \cdot \Psi_{JT})^c$<br>$T_{PCB} + (P \cdot \Psi_{JB})^d$<br>$T_A + (P \cdot \Theta_{JA})^e$<br>$T_B + (P \cdot \Theta_{JB})^{fg}$ | °C   |

- a. For more details about thermal metrics and definitions, see the *Semiconductor and IC Package Thermal Metrics Application Report* (literature number [SPRA953](#)).
- b. Junction to ambient thermal resistance ( $\Theta_{JA}$ ), junction to board thermal resistance ( $\Theta_{JB}$ ), and junction to case thermal resistance ( $\Theta_{JC}$ ) numbers are determined by a package simulator.
- c.  $T_C$  is the case temperature and P is the device power consumption.
- d.  $T_{PCB}$  is the temperature of the board acquired by following the steps listed in the EAI/JESD 51-8 standard summarized in the *Semiconductor and IC Package Thermal Metrics Application Report* (literature number [SPRA953](#)). P is the device power consumption.
- e. Because  $\Theta_{JA}$  is highly variable and based on factors such as board design, chip/pad size, altitude, and external ambient temperature, it is recommended that equations containing  $\Psi_{JT}$  and  $\Psi_{JB}$  be used for best results.
- f.  $T_B$  is temperature of the board.
- g.  $\Theta_{JB}$  is not a pure reflection of the internal resistance of the package because it includes the resistance of the testing board and environment. It is recommended that equations containing  $\Psi_{JT}$  and  $\Psi_{JB}$  be used for best results.

## 29.3 Recommended Operating Conditions

The following sections describe the recommended DC operating conditions and GPIO operating characteristics for the device.

### 29.3.1 DC Operating Conditions

**Table 29-6. Recommended DC Operating Conditions**

| Parameter                     | Parameter Name                                   | Min  | Nom | Max  | Unit |
|-------------------------------|--|------|-----|------|------|
| V <sub>DD</sub>               | V <sub>DD</sub> supply voltage                   | 2.97 | 3.3 | 3.63 | V    |
| V <sub>DDA</sub> <sup>a</sup> | V <sub>DDA</sub> supply voltage                  | 2.97 | 3.3 | 3.63 | V    |
| V <sub>DDC</sub>              | V <sub>DDC</sub> supply voltage, Run mode        | 1.14 | 1.2 | 1.32 | V    |
| V <sub>DDCDS</sub>            | V <sub>DDC</sub> supply voltage, Deep-Sleep mode | 0.85 | -   | 0.95 | V    |

a. To ensure proper operation, V<sub>DDA</sub> must be powered up before V<sub>DD</sub> if sourced from different supplies, or connected to the same supply as V<sub>DD</sub>. There is not a restriction on order for powering off.

### 29.3.2 Recommended GPIO Operating Characteristics

Two types of pads are provided on the device:

- Fast GPIO pads: These pads provide variable, programmable drive strength and optimized voltage output levels.
- Slow GPIO pads: These pads provide 2-mA drive strength and are designed to be sensitive to voltage inputs. The following GPIOs port pins are designed with Slow GPIO Pads:
  - PJ1

All other GPIOs have a fast GPIO pad-type.

**Note:** Port pins PL6 and PL7 operate as Fast GPIO pads, but have 4-mA drive capability only. GPIO register controls for drive strength, slew rate and open drain have no effect on these pins. The registers which have no effect are as follows: **GPIODR2R**, **GPIODR4R**, **GPIODR8R**, **GPIODR12R**, **GPIOSLR**, and **GPIOODR**.

**Note:** Port pins PM[7:4] operate as Fast GPIO pads but support only 2-, 4-, 6-, and 8-mA drive capability. 10- and 12-mA drive are not supported. All standard GPIO register controls, except for the **GPIODR12R** register, apply to these port pins.

Table 29-7 on page 1707 detail the GPIO operating conditions for these two different pad types.

**Table 29-7. Recommended FAST GPIO Pad Operating Conditions**

| Parameter        | Parameter Name                                  | Min                    | Nom | Max                    | Unit |
|------------------|---|------------------------|-----|------------------------|------|
| V <sub>IH</sub>  | Fast GPIO high-level input voltage              | 0.65 * V <sub>DD</sub> | -   | 4                      | V    |
| I <sub>IH</sub>  | Fast GPIO high-level input current <sup>a</sup> | -                      | -   | 300                    | nA   |
| V <sub>IL</sub>  | Fast GPIO low-level input voltage               | 0                      | -   | 0.35 * V <sub>DD</sub> | V    |
| I <sub>IL</sub>  | Fast GPIO low-level input current <sup>a</sup>  | -                      | -   | -200                   | nA   |
| V <sub>HYS</sub> | Fast GPIO Input Hysteresis                      | 0.49                   | -   | -                      | V    |
| V <sub>OH</sub>  | Fast GPIO High-level output voltage             | 2.4                    | -   | -                      | V    |
| V <sub>OL</sub>  | Fast GPIO Low-level output voltage              | -                      | -   | 0.40                   | V    |

**Table 29-7. Recommended FAST GPIO Pad Operating Conditions (continued)**

| Parameter | Parameter Name   | Min  | Nom | Max | Unit |
|-----------|--|------|-----|-----|------|
| $I_{OH}$  | Fast GPIO High-level source current, $V_{OH}=2.4\text{ V}^b$ |      |     |     |      |
|           | 2-mA Drive   | 2.0  | -   | -   | mA   |
|           | 4-mA Drive   | 4.0  | -   | -   | mA   |
|           | 8-mA Drive   | 8.0  | -   | -   | mA   |
|           | 10-mA Drive  | 10.0 | -   | -   | mA   |
|           | 12-mA Drive  | 12.0 | -   | -   | mA   |
| $I_{OL}$  | Fast GPIO Low-level sink current, $V_{OL}=0.4\text{ V}^b$    |      |     |     |      |
|           | 2-mA Drive   | 2.0  | -   | -   | mA   |
|           | 4-mA Drive   | 4.0  | -   | -   | mA   |
|           | 8-mA Drive   | 8.0  | -   | -   | mA   |
|           | 10-mA Drive  | 10.0 | -   | -   | mA   |
|           | 12-mA Drive  | 12.0 | -   | -   | mA   |
|           | 12-mA Drive overdriven to 18-mA                              | 18.0 | -   | -   | mA   |

a. Output/pull-up/pull-down disabled; only input enabled

b.  $I_O$  specifications reflect the maximum current where the corresponding output voltage meets the  $V_{OH}/V_{OL}$  thresholds.  $I_O$  current can exceed these limits (subject to absolute maximum ratings).

**Table 29-8. Recommended Slow GPIO Pad Operating Conditions**

| Parameter | Parameter Name                                     | Min             | Nom | Max             | Unit |
|-----------|--|-----------------|-----|-----------------|------|
| $V_{IH}$  | Slow GPIO high-level input voltage                 | $0.65 * V_{DD}$ | -   | 4               | V    |
| $I_{IH}$  | Slow GPIO high-level input current <sup>a</sup>    | -               | -   | 4.1             | nA   |
| $V_{IL}$  | Slow GPIO low-level input voltage                  | 0               | -   | $0.35 * V_{DD}$ | V    |
| $I_{IL}$  | Slow GPIO low-level input current <sup>a</sup>     | -               | -   | -1              | nA   |
| $V_{HYS}$ | Slow GPIO Input Hysteresis                         | 0.49            | -   | -               | V    |
| $V_{OH}$  | Slow GPIO High-level output voltage                | 2.4             | -   | -               | V    |
| $V_{OL}$  | Slow GPIO Low-level output voltage                 | -               | -   | 0.4             | V    |
| $I_{OH}$  | High-level source current, $V_{OH}=2.4\text{ V}^b$ |                 |     |                 |      |
|           | 2-mA Drive   | 2.0             | -   | -               | mA   |
| $I_{OL}$  | Low-level sink current, $V_{OL}=0.4\text{ V}^b$    |                 |     |                 |      |
|           | 2-mA Drive   | 2.0             | -   | -               | mA   |

a. Output/pull-up/pull-down disabled; only input enabled.

b.  $I_O$  specifications reflect the maximum current where the corresponding output voltage meets the  $V_{OH}/V_{OL}$  thresholds.  $I_O$  current can exceed these limits (subject to absolute maximum ratings).

### 29.3.2.1 GPIO Current Restrictions

**Table 29-9. GPIO Current Restrictions<sup>a</sup>**

| Parameter  | Parameter Name  | Min | Nom | Max | Unit |
|------------|---|-----|-----|-----|------|
| $I_{MAXL}$ | Cumulative maximum GPIO current per side, left <sup>b</sup>   | -   | -   | 110 | mA   |
| $I_{MAXB}$ | Cumulative maximum GPIO current per side, bottom <sup>b</sup> | -   | -   | 116 | mA   |
| $I_{MAXR}$ | Cumulative maximum GPIO current per side, right <sup>b</sup>  | -   | -   | 110 | mA   |

**Table 29-9. GPIO Current Restrictions (continued)**

| Parameter  | Parameter Name   | Min | Nom | Max | Unit |
|------------|--|-----|-----|-----|------|
| $I_{MAXT}$ | Cumulative maximum GPIO current per side, top <sup>b</sup> | -   | -   | 88  | mA   |

a. Based on design simulations, not tested in production.

b. Sum of sink and source current for GPIOs as shown in Table 29-10 on page 1709.

**Table 29-10. Maximum GPIO Package Side Assignments**

| Side   | GPIOs   |
|--------|---|
| Left   | PB[6-7], PC[4-7], PD[0-3], PE[0-3], PH[0-7], PJ[6-7], PK[0-3], PQ[0-3,7], PR[0-5] |
| Bottom | PA[0-7], PF[0-7], PG[0-7], PK[4-7], PN[6-7], PR[3,6-7], PQ[5-6], PS[4-7], PT[0-1] |
| Right  | PB[0-3], PJ[2-5], PL[0-5,6-7], PM[0-7], PT[2-3]                                   |
| Top    | PB[4-5], PC[0-3], PD[4-7], PE[4-7], PJ[0-1], PN[0-5], PP[0-7], PQ[4], PS[0-3],    |

**I/O Reliability**

For typical continuous drive applications, I/O pins configured between 2 mA and 12 mA and operating at -40 to 85°C, meet the standard 10-year lifetime reliability. If a continuous current sink of 18 mA is required, then operation is limited to 0 to 75°C in order to meet the standard 10-year reliability.

At 105°C, I/O configured for continuous drive meet the standard 2.5 year lifetime reliability.

In typical switching applications (40% switch rate) operating at -40 to 85°C, all I/O configurations except 2 mA meet the standard 10-year lifetime reliability with 50-pF loading. By limiting the capacitive loading to 20 pF for an I/O configured to 2 mA, the 10-year lifetime reliability can be met at -40 to 85°C.

In typical switching applications (40% switch rate) operating at 105°C, all I/O configurations except 2 mA meet the standard 2.5-year lifetime reliability. By reducing the capacitive loading to 20 pF with a typical switching rate at 105°C, a 2-mA I/O configuration meets a 2.5 year lifetime reliability.

## 29.4 Load Conditions

Table 29-11 on page 1710 contains the load conditions used for timing measurements.

**Figure 29-1. Load Conditions**

**Table 29-11. Load Conditions**

| Signals                               | Load Value ( $C_L$ ) |
|---------------------------------------|----------------------|
| EPI0S[35:0] SDRAM interface           | 30 pF                |
| EPI0S[35:0] General-Purpose interface |                      |
| EPI0S[35:0] Host-Bus interface        | 40 pF                |
| EPI0S[35:0] PSRAM interface           |                      |

## 29.5 JTAG and Boundary Scan

Table 29-12. JTAG Characteristics

| Parameter No. | Parameter       | Parameter Name  | Min | Nom         | Max | Unit |
|---------------|-----------------|---|-----|-------------|-----|------|
| J1            | $F_{TCK}$       | TCK operational clock frequency <sup>a</sup>                              | 0   | -           | 10  | MHz  |
| J2            | $T_{TCK}$       | TCK operational clock period  | 100 | -           | -   | ns   |
| J3            | $T_{TCK\_LOW}$  | TCK clock Low time  | -   | $t_{TCK}/2$ | -   | ns   |
| J4            | $T_{TCK\_HIGH}$ | TCK clock High time   | -   | $t_{TCK}/2$ | -   | ns   |
| J5            | $T_{TCK\_R}$    | TCK rise time   | 0   | -           | 10  | ns   |
| J6            | $T_{TCK\_F}$    | TCK fall time   | 0   | -           | 10  | ns   |
| J7            | $T_{TMS\_SU}$   | TMS setup time to TCK rise  | 8   | -           | -   | ns   |
| J8            | $T_{TMS\_HLD}$  | TMS hold time from TCK rise   | 4   | -           | -   | ns   |
| J9            | $T_{TDI\_SU}$   | TDI setup time to TCK rise  | 18  | -           | -   | ns   |
| J10           | $T_{TDI\_HLD}$  | TDI hold time from TCK rise   | 4   | -           | -   | ns   |
| J11           | $T_{TDO\_ZDV}$  | TCK fall to Data Valid from High-Z, 2-mA drive                            | -   | 13          | 35  | ns   |
|               |                 | TCK fall to Data Valid from High-Z, 4-mA drive                            |     | 9           | 26  | ns   |
|               |                 | TCK fall to Data Valid from High-Z, 8-mA drive                            |     | 8           | 26  | ns   |
|               |                 | TCK fall to Data Valid from High-Z, 8-mA drive with slew rate control     |     | 10          | 29  | ns   |
|               |                 | TCK fall to Data Valid from High-Z, 10-mA drive                           |     | 11          | 13  | ns   |
|               |                 | TCK fall to Data Valid from High-Z, 12-mA drive                           |     | 11          | 14  | ns   |
| J12           | $T_{TDO\_DV}$   | TCK fall to Data Valid from Data Valid, 2-mA drive                        | -   | 14          | 20  | ns   |
|               |                 | TCK fall to Data Valid from Data Valid, 4-mA drive                        |     | 10          | 26  | ns   |
|               |                 | TCK fall to Data Valid from Data Valid, 8-mA drive                        |     | 8           | 21  | ns   |
|               |                 | TCK fall to Data Valid from Data Valid, 8-mA drive with slew rate control |     | 10          | 26  | ns   |
|               |                 | TCK fall to Data Valid from Data Valid, 10-mA drive                       |     | 12          | 14  | ns   |
|               |                 | TCK fall to Data Valid from Data Valid, 12-mA drive                       |     | 12          | 15  | ns   |
| J13           | $T_{TDO\_DVZ}$  | TCK fall to High-Z from Data Valid, 2-mA drive                            | -   | 7           | 16  | ns   |
|               |                 | TCK fall to High-Z from Data Valid, 4-mA drive                            |     | 7           | 16  | ns   |
|               |                 | TCK fall to High-Z from Data Valid, 8-mA drive                            |     | 7           | 16  | ns   |
|               |                 | TCK fall to High-Z from Data Valid, 8-mA drive with slew rate control     |     | 8           | 19  | ns   |
|               |                 | TCK fall to High-Z from Data Valid, 10-mA drive                           |     | 20          | 22  | ns   |
|               |                 | TCK fall to High-Z from Data Valid, 12-mA drive                           |     | 20          | 25  | ns   |

a. A ratio of at least 8:1 must be kept between the system clock and TCK.

## 29.6 Power and Brown-Out

Table 29-13. Power and Brown-Out Levels

| Parameter No. | Parameter          | Parameter Name                                | Min  | Nom  | Max      | Unit    |
|---------------|--------------------|---|------|------|----------|---------|
| P1            | $T_{VDDA\_RISE}$   | Analog Supply voltage ( $V_{DDA}$ ) rise time | -    | -    | $\infty$ | $\mu s$ |
| P2            | $T_{VDD\_RISE}$    | I/O Supply voltage ( $V_{DD}$ ) rise time     | -    | -    | $\infty$ | $\mu s$ |
| P3            | $T_{VDDC\_RISE}^a$ | Core Supply Voltage ( $V_{DDC}$ ) rise time   | 10   | -    | 150      | $\mu s$ |
| P4            | $V_{POR}$          | Power-On Reset Threshold (Rising Edge)        | 1.98 | 2.35 | 2.72     | V       |
|               |                    | Power-On Reset Threshold (Falling Edge)       | 1.84 | 2.20 | 2.56     | V       |
|               |                    | Power-On Reset Hysteresis                     | 0.06 | 0.15 | 0.24     | V       |
| P5            | $V_{DDA\_POK}$     | $V_{DDA}$ Power-OK Threshold (Rising Edge)    | 2.67 | 2.82 | 2.97     | V       |
| P6            | $V_{DDA\_BOR0}$    | $V_{DDA}$ Brown-Out Reset Threshold           | 2.71 | 2.80 | 2.89     | V       |
| P7            | $V_{DD\_POK}$      | $V_{DD}$ Power-OK Threshold (Rising Edge)     | 2.65 | 2.80 | 2.90     | V       |
|               |                    | $V_{DD}$ Power-OK Threshold (Falling Edge)    | 2.67 | 2.76 | 2.85     | V       |
| P8            | $V_{DD\_BOR0}$     | $V_{DD}$ Brown-Out Reset Threshold            | 2.77 | 2.86 | 2.95     | V       |
| P9            | $V_{DDC\_POK}$     | $V_{DDC}$ Power-OK Threshold (Rising Edge)    | 0.85 | 0.95 | 1.10     | V       |
|               |                    | $V_{DDC}$ Power-OK Threshold (Falling Edge)   | 0.71 | 0.80 | 0.85     | V       |

a. The MIN and MAX values are based on an external filter capacitor load within the range of  $C_{LDO}$ . Please refer to "On-Chip Low Drop-Out (LDO) Regulator" on page 1721 for the  $C_{LDO}$  value.

### 29.6.1 $V_{DDA}$ Levels

The  $V_{DDA}$  supply has three monitors:

- Power-On Reset (POR)
- Power-OK (POK)
- Brown Out Reset (BOR)

The POR monitor is used to keep the analog circuitry in reset until the  $V_{DDA}$  supply has reached the correct range for the analog circuitry to begin operating. The POK monitor is used to keep the digital circuitry in reset until the  $V_{DDA}$  power supply is at an acceptable operational level. The digital reset is only released when the Power-On Reset has deasserted and all of the Power-OK monitors for each of the supplies indicate that power levels are in operational ranges. The BOR monitor is used to generate a reset to the device or assert an interrupt if the  $V_{DDA}$  supply drops below its operational range.

**Note:**  $V_{DDA}$  BOR and  $V_{DD}$  BOR events are a combined BOR to the system logic, such that if either BOR event occurs, the following bits are affected:

- **BORRIS** bit in the **Raw Interrupt Status (RIS)** register, System Control offset 0x050. See page 262.
- **BORMIS** bit in the **Masked Interrupt Status and Clear (MISC)** register, System Control offset 0x058. This bit is set only if the **BORIM** bit in the **Interrupt Mask Control (IMC)** register has been set. See page 264 and page 266.

- BOR bit in the **Reset Cause (RESC)** register, System Control offset 0x05C. This bit is set only if either of the BOR events have been configured to initiate a reset. See page 268.

In addition, the following bits control both BOR events:

- BORIM bit in the **Interrupt Mask Control (IMC)** register, System Control offset 0x054.
- VDDA\_UBOR0 and VDD\_UBOR0 bits in the **Power-Temperature Cause (PWRTC)** register.

Please refer to “System Control” on page 222 for more information on how to configure these registers.

Figure 29-4 on page 1714 shows the relationship between  $V_{DDA}$ , POK, POR and a BOR event.

**Figure 29-4. Power and Brown-Out Assertions vs  $V_{DDA}$  Levels**

### 29.6.2 $V_{DD}$ Levels

The  $V_{DD}$  supply has two monitors:

- Power-OK (POK)
- Brown Out Reset (BOR)

The POK monitor is used to keep the digital circuitry in reset until the  $V_{DD}$  power supply is at an acceptable operational level. The digital reset is only released when the Power-On Reset has deasserted and all of the Power-OK monitors for each of the supplies indicate that power levels are

in operational ranges. The BOR monitor is used to generate a reset to the device or assert an interrupt if the  $V_{DD}$  supply drops below its operational range.

**Note:**  $V_{DDA}$  BOR and  $V_{DD}$  BOR events are a combined BOR to the system logic, such that if either BOR event occurs, the following bits are affected:

- BORRIS bit in the **Raw Interrupt Status (RIS)** register, System Control offset 0x050. See page 262.
- BORMIS bit in the **Masked Interrupt Status and Clear (MISC)** register, System Control offset 0x058. This bit is set only if the BORIM bit in the **Interrupt Mask Control (IMC)** register has been set. See page 264 and page 266.
- BOR bit in the **Reset Cause (RESC)** register, System Control offset 0x05C. This bit is set only if either of the BOR events have been configured to initiate a reset. See page 268.

In addition, the following bits control both BOR events:

- BORIM bit in the **Interrupt Mask Control (IMC)** register, System Control offset 0x054.
- VDDA\_UBOR0 and VDD\_UBOR0 bits in the **Power-Temperature Cause (PWRTC)** register.

Please refer to “System Control” on page 222 for more information on how to configure these registers.

Figure 29-5 on page 1715 shows the relationship between  $V_{DD}$ , POK, POR and a BOR event.

**Figure 29-5. Power and Brown-Out Assertions vs  $V_{DD}$  Levels**

### 29.6.3 $V_{DDC}$ Levels

The  $V_{DDC}$  supply has one monitor, the Power-OK (POK). The POK monitor is used to keep the digital circuitry in reset until the  $V_{DDC}$  power supply is at an acceptable operational level. The digital reset is only released when the Power-On Reset has deasserted and all of the Power-OK monitors for each of the supplies indicate that power levels are in operational ranges. Figure 29-6 on page 1716 shows the relationship between POK and  $V_{DDC}$ .

Figure 29-6. POK Assertion vs  $V_{DDC}$

## 29.6.4 Response

### 29.6.4.1 $V_{DD}$ Glitch Response

Figure 29-7 on page 1716 shows the response of the BOR and the POR circuit to glitches on the VDD supply.

Figure 29-7. POR-BOR  $V_{DD}$  Glitch Response

### 29.6.4.2 $V_{DD}$ Droop Response

Figure 29-8 on page 1717 shows the response of the BOR and the POR monitors to a drop on the VDD supply.

Figure 29-8. POR-BOR  $V_{DD}$  Droop Response

## 29.7 Reset

**Table 29-14. Reset Characteristics<sup>a</sup>**

| Parameter No. | Parameter        | Parameter Name  | Min  | Nom                                 | Max               | Unit          |
|---------------|------------------|---|------|-------------------------------------|-------------------|---------------|
| R1            | $T_{DPORDLY}^b$  | Digital POR to Internal Reset assertion delay <sup>c</sup>                    | 0.44 | -                                   | 126               | $\mu\text{s}$ |
| R2            | $T_{IRTOU}^{bd}$ | Standard Internal Reset time  | -    | 14                                  | 16                | ms            |
|               |                  | Internal Reset time with recovery code repair (program or erase) <sup>e</sup> | 24.4 | -                                   | 6400 <sup>f</sup> | ms            |
| R3            | $T_{BOROPLY}^b$  | BOR0 to Internal Reset assertion delay <sup>c</sup>                           | 0.44 | -                                   | 125               | $\mu\text{s}$ |
| R4            | $T_{RSTMIN}$     | Minimum $\overline{\text{RST}}$ pulse width                                   | -    | 0.25 <sup>g</sup> /100 <sup>h</sup> | -                 | $\mu\text{s}$ |
| R5            | $T_{IRHWDLY}$    | $\overline{\text{RST}}$ to Internal Reset assertion delay                     | -    | 0.85                                | -                 | $\mu\text{s}$ |
| R6            | $T_{IRSWR}^b$    | Internal reset timeout after software-initiated system reset                  | -    | 2.44                                | -                 | $\mu\text{s}$ |
| R7            | $T_{IRWDR}^b$    | Internal reset timeout after Watchdog reset                                   | -    | 2.44                                | -                 | $\mu\text{s}$ |
| R8            | $T_{IRMFR}^b$    | Internal reset timeout after MOSC failure reset                               | -    | 2.44                                | -                 | $\mu\text{s}$ |

- a. Minimum timings are for reset assertion using PIOSC as a clock source. Maximum timings are for reset assertion using LFIOSC in Deep-Sleep Operation.
- b. These values are based on simulation.
- c. Timing values are dependent on the  $V_{DD}$  power-down ramp rate.
- d. This is the delay from the time POR is released until the reset vector is fetched.
- e. This parameter applies only in situations where a power-loss or brown-out event occurs during an EEPROM program or erase operation, and EEPROM needs to be repaired (which is a rare case). For all other sequences, there is no impact to normal Power-On Reset (POR) timing. This delay is in addition to other POR delays.
- f. This value represents the maximum internal reset time when the EEPROM reaches its endurance limit.
- g. Standard operation.
- h. Deep-Sleep operation with PIOSC powered down.

**Figure 29-9. Digital Power-On Reset Timing**

The digital Power-On Reset is only released when the analog Power-On Reset has deasserted and all of the Power-OK monitors for each of the supplies indicate that power levels are in operational ranges.

## 29.8 On-Chip Low Drop-Out (LDO) Regulator

Table 29-15. LDO Regulator Characteristics

| Parameter    | Parameter Name  | Min  | Nom | Max  | Unit             |
|--------------|---|------|-----|------|------------------|
| $C_{LDO}$    | External filter capacitor size for internal power supply <sup>a</sup> | 2.5  | -   | 4.0  | $\mu\text{F}$    |
| ESR          | Filter capacitor equivalent series resistance                         | 0    | -   | 100  | $\text{m}\Omega$ |
| ESL          | Filter capacitor equivalent series inductance                         | -    | -   | 0.5  | $\text{nH}$      |
| $V_{LDO}$    | LDO output voltage, Run mode  | 1.13 | 1.2 | 1.27 | V                |
| $I_{INRUSH}$ | Inrush current  | 50   | -   | 250  | $\text{mA}$      |

a. The capacitor should be connected as close as possible to pin E10.

## 29.9 Clocks

The following sections provide specifications on the various clock sources and mode.

### 29.9.1 PLL Specifications

The following tables provide specifications for using the PLL.

**Table 29-16. Phase Locked Loop (PLL) Characteristics**

| Parameter             | Parameter Name   | Min | Nom | Max                            | Unit |
|-----------------------|--|-----|-----|--------------------------------|------|
| F <sub>REF_XTAL</sub> | Crystal reference  | 5   | -   | 25                             | MHz  |
| F <sub>REF_EXT</sub>  | External clock reference   | 5   | -   | 25                             | MHz  |
| F <sub>PLL</sub>      | PLL VCO frequency at 1.2V <sup>a</sup>   | -   | -   | 480                            | MHz  |
| F <sub>PLLS</sub>     | PLL VCO frequency at 0.9V <sup>b</sup>   | -   | -   | 480                            | MHz  |
| T <sub>READY</sub>    | PLL lock time (enabling the PLL) when PLL is transitioning from power down to power up | -   | -   | 512 * (reference clock period) | μs   |
|                       | PLL lock time when the PLL VCO frequency is changed (PLL is already enabled)           | -   | -   | 128 * (reference clock period) | μs   |
|                       | PLL lock time, changing the OSCSRC between MOSC and PIOSC                              | -   | -   | 128 * (reference clock period) | μs   |

a. PLL frequency is manually calculated using the values in the PLLFREQ0 and PLLFREQ1 registers.

b. If the LDO is dropped to 0.9V, the system must be run 1/4 of the maximum frequency at most. The Q value in the **PLLFREQ1** register must be set to 0x3 rather than using the **PSYSDIV** field in the **RSCLKCFG** register for the divisor.

#### 29.9.1.1 PLL Configuration

The PLL is disabled by default during power-on reset and is enabled later by software if required. Software specifies the output divisor to set the system clock frequency and enables the PLL to drive the output. The PLL is controlled using the **PLLFREQ0**, **PLLFREQ1** and **PLLSTAT** registers. Changes made to these registers do not become active until after the **NEWFREQ** bit in the **RSCLKCFG** register is enabled.

The clock source for the main PLL is selected by configuring the **PLLSRC** field in the **Run and Sleep Clock Configuration (RSCLKCFG)** register.

The PLL allows for the generation of system clock frequencies in excess of the reference clock provided. The reference clocks for the PLL are the PIOSC and the MOSC. The PLL is controlled by two registers, **PLLFREQ0** and **PLLFREQ1**. The PLL VCO frequency ( $f_{VCO}$ ) is determined through the following calculation:

$$f_{VCO} = f_{IN} * MDIV$$

where

$$f_{IN} = f_{XTAL} / ((Q+1)(N+1)) \text{ or } f_{PIOSC} / ((Q+1)(N+1))$$

$$MDIV = MINT + (MFRAC / 1024)$$

The Q and N values are programmed in the **PLLFREQ1** register. Note that to reduce jitter, MFRAC should be programmed to 0x0.

When the PLL is active, the system clock frequency (SysClk) is calculated using the following equation:

$$\text{SysClk} = f_{\text{VCO}} / (\text{PSYSDIV} + 1)$$

The PLL system divisor factor (PSYSDIV) determines the value of the system clock. Table 5-6 on page 239 shows how the system divisor encodings affect the system clock frequency when the  $f_{\text{VCO}} = 480$  MHz.

**Table 29-17. System Divisor Factors for  $f_{\text{VCO}}=480$  MHz**

| System Clock (SYSCLK) (MHz) | $f_{\text{VCO}}$ (MHz)= 480 MHz           |
|-----------------------------|---|
|                             | System Divisors (PSYSDIV +1) <sup>a</sup> |
| 120                         | 4   |
| 60                          | 8   |
| 48                          | 10  |
| 30                          | 16  |
| 24                          | 20  |
| 12                          | 40  |
| 6                           | 80  |

a. The use of non-integer divisors introduce additional jitter which may affect interface performance.

If the main oscillator provides the clock reference to the PLL, the translation provided by hardware and used to program the PLL is available for software in the **PLL Frequency n (PLLREQn)** registers (see page 293). The internal translation provides a translation within  $\pm 1\%$  of the targeted PLL VCO frequency. Table 5-7 on page 239 shows the actual PLL frequency and error for a given crystal choice.

Table 5-7 on page 239 provides examples of the programming expected for the **PLLREQ0** and **PLLREQ1** registers. The first column specifies the input crystal frequency and the last column displays the PLL frequency given the values of MINT and N, when Q=0.

**Table 29-18. Actual PLL Frequency<sup>a</sup>**

| Crystal Frequency (MHz) | MINT (Decimal Value) | MINT (Hexadecimal Value) | N   | Reference Frequency (MHz) <sup>b</sup> | PLL Frequency (MHz) |
|-------------------------|----------------------|--------------------------|-----|--|---------------------|
| 5                       | 64                   | 0x40                     | 0x0 | 5                                      | 320                 |
| 6                       | 160                  | 0x35                     | 0x2 | 2                                      | 320                 |
| 8                       | 40                   | 0x28                     | 0x0 | 8                                      | 320                 |
| 10                      | 32                   | 0x20                     | 0x0 | 10                                     | 320                 |
| 12                      | 80                   | 0x50                     | 0x2 | 4                                      | 320                 |
| 16                      | 20                   | 0x14                     | 0x0 | 16                                     | 320                 |
| 18                      | 160                  | 0xA0                     | 0x8 | 2                                      | 320                 |
| 20                      | 16                   | 0x10                     | 0x0 | 20                                     | 320                 |
| 24                      | 40                   | 0x28                     | 0x2 | 8                                      | 320                 |
| 25                      | 64                   | 0x40                     | 0x4 | 5                                      | 320                 |
| 5                       | 96                   | 0x60                     | 0x0 | 5                                      | 480                 |
| 6                       | 80                   | 0x50                     | 0x0 | 6                                      | 480                 |
| 8                       | 60                   | 0x3C                     | 0x0 | 8                                      | 480                 |
| 10                      | 48                   | 0x30                     | 0x0 | 10                                     | 480                 |
| 12                      | 40                   | 0x28                     | 0x0 | 12                                     | 480                 |

Table 29-18. Actual PLL Frequency (continued)

| Crystal Frequency (MHz) | MINT (Decimal Value) | MINT (Hexadecimal Value) | N   | Reference Frequency (MHz) <sup>b</sup> | PLL Frequency (MHz) |
|-------------------------|----------------------|--------------------------|-----|--|---------------------|
| 16                      | 30                   | 0x1E                     | 0x0 | 16                                     | 480                 |
| 18                      | 80                   | 0x50                     | 0x2 | 6                                      | 480                 |
| 20                      | 24                   | 0x18                     | 0x0 | 20                                     | 480                 |
| 24                      | 20                   | 0x14                     | 0x0 | 24                                     | 480                 |
| 25                      | 96                   | 0x60                     | 0x4 | 5                                      | 480                 |

a. For all examples listed, Q=0

b. For a given crystal frequency, N should be chosen such that the reference frequency is within 4 to 30 MHz.

## 29.9.2 PIOSC Specifications

Table 29-19. PIOSC Clock Characteristics

| Parameter          | Parameter Name   | Min | Nom | Max   | Unit |
|--------------------|--|-----|-----|-------|------|
| F <sub>PIOSC</sub> | Factory calibration, 0 to +105°C:<br>Internal 16-MHz precision oscillator frequency variance across voltage and temperature range when factory calibration is used | -   | -   | ±4.5% | -    |
|                    | Factory calibration, -40°C to <0°C   | -   | -   | ±10%  | -    |
|                    | Recalibration:<br>Internal 16-MHz precision oscillator frequency variance when recalibration is used at a specific temperature                                     | -   | -   | ±1%   | -    |
| T <sub>START</sub> | PIOSC startup time <sup>a</sup>  | -   | -   | 1     | μs   |

a. PIOSC startup time is part of reset and is included in the internal reset timeout value (T<sub>IRTOU</sub>) given in Table 29-14 on page 1718. Note that the T<sub>START</sub> value is based on simulation.

## 29.9.3 Low-Frequency Internal Oscillator Specifications

Table 29-20. Low-Frequency Oscillator Characteristics

| Parameter           | Parameter Name                              | Min | Nom | Max | Unit |
|---------------------|---|-----|-----|-----|------|
| F <sub>LFIOSC</sub> | Internal low-frequency oscillator frequency | 10  | 33  | 75  | KHz  |

## 29.9.4 Hibernation Clock Source Specifications

Table 29-21. Hibernation Internal Low Frequency Oscillator Clock Characteristics

| Parameter              | Parameter Name  | Min | Nom | Max | Unit |
|------------------------|---|-----|-----|-----|------|
| F <sub>HIBLFIOSC</sub> | Internal Low Frequency Hibernation oscillator frequency | 10  | 33  | 90  | KHz  |

Table 29-22. Hibernation External Oscillator (XOSC) Input Characteristics

| Parameter                         | Parameter Name  | Min | Nom    | Max | Unit |
|-----------------------------------|---|-----|--------|-----|------|
| F <sub>HIBXOSC</sub> <sup>a</sup> | Parallel resonance frequency                                | -   | 32.768 | -   | KHz  |
| C <sub>1</sub> , C <sub>2</sub>   | External load capacitance on XOSC0, XOSC1 pins <sup>b</sup> | 12  | -      | 24  | pF   |
| C <sub>PKG</sub>                  | Device package stray shunt capacitance <sup>b</sup>         | -   | 0.5    | -   | pF   |
| C <sub>PCB</sub>                  | PCB stray shunt capacitance <sup>b</sup>                    | -   | 0.5    | -   | pF   |
| C <sub>SHUNT</sub>                | Total shunt capacitance <sup>b</sup>                        | -   | -      | 4   | pF   |

**Table 29-22. Hibernation External Oscillator (XOSC) Input Characteristics (continued)**

| Parameter                     | Parameter Name   | Min          | Nom | Max               | Unit |
|-------------------------------|--|--------------|-----|-------------------|------|
| ESR                           | Crystal effective series resistance, OSCDRV = 0 <sup>c</sup>                                 | -            | -   | 50                | kΩ   |
|                               | Crystal effective series resistance, OSCDRV = 1 <sup>c</sup>                                 | -            | -   | 75                | kΩ   |
| DL                            | Oscillator output drive level  | -            | -   | 0.25              | μW   |
| T <sub>START</sub>            | Oscillator startup time, when using a crystal <sup>d</sup>                                   | -            | 600 | 1500 <sup>e</sup> | ms   |
| V <sub>IH</sub> <sup>f</sup>  | CMOS input high level, when using an external oscillator with Supply > 3.3 V                 | 2.64         | -   | -                 | V    |
|                               | CMOS input high level, when using an external oscillator with 1.8 V ≤ Supply ≤ 3.3 V         | 0.8 * Supply | -   | -                 | V    |
| V <sub>IL</sub> <sup>f</sup>  | CMOS input low level, when using an external oscillator with 1.8 V ≤ Supply ≤ 3.63 V         | -            | -   | 0.2 * Supply      | V    |
| V <sub>HYS</sub> <sup>f</sup> | CMOS input buffer hysteresis, when using an external oscillator with 1.8 V ≤ Supply ≤ 3.63 V | 360          | 960 | 1390              | mV   |
| DC <sub>HIBOSC_EXT</sub>      | External single-Ended (Bypass) reference duty cycle  | 30           | -   | 70                | %    |

a. The HIB XOSC pins are non-failsafe and must follow the limits detailed in “Non-Power I/O Pins” on page 1738.

b. See information below table.

c. Crystal ESR specified by crystal manufacturer.

d. Oscillator startup time is specified from the time the oscillator is enabled to when it reaches a stable point of oscillation such that the internal clock is valid.

e. Only valid for recommended supply conditions. Measured with OSCDRV bit set (high drive strength enabled, 24 pF).

f. Specification is relative to the larger of V<sub>DD</sub> or V<sub>BAT</sub>.

The load capacitors added on the board, C<sub>1</sub> and C<sub>2</sub>, should be chosen such that the following equation is satisfied (see Table 29-22 on page 1724 for typical values).

- C<sub>L</sub> = load capacitance specified by crystal manufacturer
- $C_L = (C_1 * C_2) / (C_1 + C_2) + C_{PKG} + C_{PCB}$
- C<sub>SHUNT</sub> = C<sub>PKG</sub> + C<sub>PCB</sub> + C<sub>0</sub> (total shunt capacitance seen across XOSC0, XOSC1)
- C<sub>PKG</sub>, C<sub>PCB</sub> as measured across the XOSC0, XOSC1 pins excluding the crystal
- Clear the OSCDRV bit in the **Hibernation Control (HIBCTL)** register for C<sub>1,2</sub> ≤ 18 pF; set the OSCDRV bit for C<sub>1,2</sub> > 18 pF.
- C<sub>0</sub> = Shunt capacitance of crystal specified by the crystal manufacturer

## 29.9.5 Main Oscillator Specifications

**Table 29-23. Main Oscillator Input Characteristics**

| Parameter                       | Parameter Name  | Min            | Nom | Max | Unit |
|---------------------------------|---|----------------|-----|-----|------|
| F <sub>MOSC</sub>               | Parallel resonance frequency                              | 4 <sup>a</sup> | -   | 25  | MHz  |
| F <sub>REF_XTAL_BYPASS</sub>    | External clock reference (PLL in BYPASS mode)             | 0              | -   | 120 | MHz  |
| C <sub>1</sub> , C <sub>2</sub> | External load capacitance on osc0, osc1 pins <sup>b</sup> | 12             | -   | 24  | pF   |
| C <sub>PKG</sub>                | Device package stray shunt capacitance <sup>b</sup>       | -              | 0.5 | -   | pF   |
| C <sub>PCB</sub>                | PCB stray shunt capacitance <sup>b</sup>                  | -              | 0.5 | -   | pF   |
| C <sub>SHUNT</sub>              | Total shunt capacitance <sup>b</sup>                      | -              | -   | 4   | pF   |

Table 29-23. Main Oscillator Input Characteristics (continued)

| Parameter             | Parameter Name  | Min                    | Nom                | Max                    | Unit |
|-----------------------|---|------------------------|--------------------|------------------------|------|
| ESR                   | Crystal effective series resistance, 4 MHz <sup>cd</sup>        | -                      | -                  | 300                    | Ω    |
|                       | Crystal effective series resistance, 6 MHz <sup>cd</sup>        | -                      | -                  | 200                    | Ω    |
|                       | Crystal effective series resistance, 8 MHz <sup>cd</sup>        | -                      | -                  | 130                    | Ω    |
|                       | Crystal effective series resistance, 12 MHz <sup>cd</sup>       | -                      | -                  | 120                    | Ω    |
|                       | Crystal effective series resistance, 16 MHz <sup>cd</sup>       | -                      | -                  | 100                    | Ω    |
|                       | Crystal effective series resistance, 25 MHz <sup>cd</sup>       | -                      | -                  | 50                     | Ω    |
| DL                    | Oscillator output drive level <sup>e</sup>                      | -                      | OSC <sub>PWR</sub> | -                      | mW   |
| T <sub>START</sub>    | Oscillator startup time, when using a crystal <sup>f</sup>      | -                      | -                  | 18                     | ms   |
| V <sub>IH</sub>       | CMOS input high level, when using an external oscillator        | 0.65 * V <sub>DD</sub> | -                  | V <sub>DD</sub>        | V    |
| V <sub>IL</sub>       | CMOS input low level, when using an external oscillator         | GND                    | -                  | 0.35 * V <sub>DD</sub> | V    |
| V <sub>HYS</sub>      | CMOS input buffer hysteresis, when using an external oscillator | 150                    | -                  | -                      | mV   |

a. 5 MHz is the minimum when using the PLL.

b. See information below table.

c. Crystal ESR specified by crystal manufacturer.

d. Crystal vendors can be contacted to confirm these specifications are met for a specific crystal part number if the vendors generic crystal datasheet show limits outside of these specifications.

e.  $OSC_{PWR} = (2 * \pi * F_P * C_L * 2.5)^2 * ESR / 2$ . An estimation of the typical power delivered to the crystal is based on the  $C_L$ ,  $F_P$  and ESR parameters of the crystal in the circuit as calculated by the  $OSC_{PWR}$  equation. Ensure that the value calculated for  $OSC_{PWR}$  does not exceed the crystal's drive-level maximum.

f. Oscillator startup time is specified from the time the oscillator is enabled to when it reaches a stable point of oscillation such that the internal clock is valid.

The load capacitors added on the board,  $C_1$  and  $C_2$ , should be chosen such that the following equation is satisfied (see Table 29-23 on page 1725 for typical values and Table 29-24 on page 1727 for detailed crystal parameter information).

- $C_L$  = load capacitance specified by crystal manufacturer
- $C_L = (C_1 * C_2) / (C_1 + C_2) + C_{SHUNT}$
- $C_{SHUNT} = C_0 + C_{PKG} + C_{PCB}$  (total shunt capacitance seen across OSC0, OSC1 crystal inputs)
- $C_{PKG}$ ,  $C_{PCB}$  = the mutual caps as measured across the OSC0, OSC1 pins excluding the crystal.
- $C_0$  = Shunt capacitance of crystal specified by the crystal manufacturer

Table 29-24 on page 1727 lists part numbers of crystals that have been simulated and confirmed to operate within the specifications in Table 29-23 on page 1725. Other crystals that have nearly identical crystal parameters can be expected to work as well.

In the table below, the crystal parameters labeled  $C_0$ ,  $C_1$  and  $L_1$  are values that are obtained from the crystal manufacturer. These numbers are usually a result of testing a relevant batch of crystals on a network analyzer. The parameters labeled ESR, DL and  $C_L$  are maximum numbers usually available in the data sheet for a crystal.

The table also includes three columns of Recommended Component Values. These values apply to system board components.  $C_1$  and  $C_2$  are the values in pico Farads of the load capacitors that should be put on each leg of the crystal pins to ensure oscillation at the correct frequency.  $R_s$  is the value in k $\Omega$  of a resistor that is placed in series with the crystal between the OSC1 pin and the crystal pin.  $R_s$  dissipates some of the power so the Max DI crystal parameter is not exceeded. Only use the recommended  $C_1$ ,  $C_2$ , and  $R_s$  values with the associated crystal part. The values in the table were used in the simulation to ensure crystal startup and to determine the worst case drive level (WC DI). The value in the WC DI column should not be greater than the Max DI Crystal parameter. The WC DI value can be used to determine if a crystal with similar parameter values but a lower Max DI value is acceptable.

Table 29-24. Crystal Parameters

- a. R<sub>S</sub> values as low as 0 Ohms can be used. Using a lower R<sub>S</sub> value will result in the WC DL to increase towards the Max DL of the crystal.
- b. Although this ESR value is outside of the recommended crystal ESR maximum for this frequency, this crystal has been simulated to confirm proper operation and is valid for use with this device.
- c. R<sub>S</sub> values as low as 500 Ohms can be used. Using a lower R<sub>S</sub> value will result in the WC DL to increase towards the Max DL of the crystal.

## 29.9.6 System Clock Specification with ADC Operation

Table 29-25. System Clock Characteristics with ADC Operation

| Parameter           | Parameter Name  | Min | Nom | Max | Unit |
|---------------------|---|-----|-----|-----|------|
| $F_{\text{sysadc}}$ | System clock frequency when the ADC module is operating (when PLL is bypassed). | -   | 16  | -   | MHz  |

## 29.9.7 System Clock Specification with USB Operation

Table 29-26. System Clock Characteristics with USB Operation

| Parameter           | Parameter Name  | Min | Nom | Max | Unit |
|---------------------|---|-----|-----|-----|------|
| $F_{\text{sysusb}}$ | System clock frequency when the USB module is operating (note that MOSC must be the clock source, either with or without using the PLL) | 30  | -   | -   | MHz  |

## 29.10 Sleep Modes

The following tables can be used to calculate the maximum wake time from Sleep or Deep Sleep depending on the specific application. Depending on the application configuration, each of the parameters, except for  $T_{FLASH}$ , add sequential latency to the wake time. Flash restoration happens in parallel to the other wake processes and its wake time is normally absorbed by the other latencies. As an example, the wake time for a device in Deep Sleep, with the PIOSC and PLL turned off and the Flash and SRAM in low power mode is calculated as follows:

$$\text{Wake Time} = T_{PIOSCDS} + T_{PLLDS} + T_{SRAML PDS}$$

$T_{FLASH}$  does not contribute to this equation since all other parameters are greater in value.

Note that in Sleep mode the wake time due to a clock source is zero because the device uses the same clock configuration in Run mode; thus, there is no latency involved with respect to the clocks.

**Table 29-27. Wake from Sleep Characteristics**

| Parameter No | Parameter      | Parameter Name   | Min | Nom | Max              | Unit          |
|--------------|----------------|--|-----|-----|------------------|---------------|
| D1           | $T_{PIOSC}$    | Time to restore PIOSC as System Clock in Sleep mode                      | -   | -   | N/A <sup>a</sup> | $\mu\text{s}$ |
| D2           | $T_{MOSC}$     | Time to restore MOSC as System Clock in Sleep mode                       | -   | -   | N/A <sup>b</sup> | $\mu\text{s}$ |
| D3           | $T_{PLL}$      | Time to restore PLL as System Clock in Sleep mode                        | -   | -   | N/A <sup>c</sup> | $\mu\text{s}$ |
| D4           | $T_{LDO}$      | Time to restore LDO to 1.2 V in Sleep mode                               | -   | -   | 39               | $\mu\text{s}$ |
| D5           | $T_{FLASH}$    | Time to restore Flash to active state from low power state in Sleep mode | -   | -   | 5                | $\mu\text{s}$ |
| D6           | $T_{SRAML P}$  | Time to restore SRAM to active state from low power state in Sleep mode  | -   | -   | 15               | $\mu\text{s}$ |
| D7           | $T_{SRAMSTBY}$ | Time to restore SRAM to active state from standby state in Sleep mode    | -   | -   | 15               | $\mu\text{s}$ |

a. Because the PIOSC is enabled in both Run and Sleep Mode for this configuration, no restoration time is required.

b. Because the MOSC is enabled in both Run and Sleep Mode for this configuration, no restoration time is required.

c. Because the PLL is enabled in both Run and Sleep Mode for this configuration, no restoration time is required.

**Table 29-28. Wake from Deep Sleep Characteristics**

| Parameter No | Parameter       | Parameter Name   | Min | Nom | Max  | Unit                                 |
|--------------|-----------------|--|-----|-----|--|--------------------------------------|
| D8           | $T_{PIOSCDS}$   | Time to restore PIOSC as System Clock in Deep Sleep Mode   | -   | -   | 14   | Deep Sleep Clock Cycles <sup>a</sup> |
| D9           | $T_{MOSCDS}$    | Time to restore MOSC as System Clock in Deep Sleep Mode    | -   | -   | 18   | ms                                   |
| D10          | $T_{PLLDS}$     | Time to restore PLL as System Clock in Deep Sleep Mode     | -   | -   | 1 cycle of Deep Sleep Clock + 512 cycles of PLL reference Clock <sup>a</sup> | clocks                               |
| D11          | $T_{LDODS}$     | Time to restore LDO to 1.2 V in Deep Sleep Mode            | -   | -   | 39   | $\mu\text{s}$                        |
| D12          | $T_{FLASHLPDS}$ | Time to restore Flash to active state from low power state | -   | -   | 5  | $\mu\text{s}$                        |
| D13          | $T_{SRAML PDS}$ | Time to restore SRAM to active state from low power state  | -   | -   | 15   | $\mu\text{s}$                        |

**Table 29-28. Wake from Deep Sleep Characteristics (continued)**

| Parameter No | Parameter               | Parameter Name  | Min | Nom | Max | Unit |
|--------------|-------------------------|---|-----|-----|-----|------|
| D14          | T <sub>SRAMSTBYDS</sub> | Time to restore SRAM to active state from standby state | -   | -   | 15  | μs   |

a. Deep Sleep Clock can vary. See page 282 for the Deep Sleep Clock options.

## 29.11 Hibernation Module

The Hibernation module requires special system implementation considerations because it is intended to power down all other sections of its host device, refer to “Hibernation Module” on page 520.

**Table 29-29. Hibernation Module Battery Characteristics**

| Parameter                        | Parameter Name                                    | Min | Nominal | Max              | Unit |
|----------------------------------|---|-----|---------|------------------|------|
| V <sub>BAT</sub>                 | Battery supply voltage                            | 1.8 | 3.0     | 3.6 <sup>a</sup> | V    |
| V <sub>BATRMP</sub> <sup>b</sup> | V <sub>BAT</sub> battery supply voltage ramp time | 0   | -       | 0.7              | V/μs |
| V <sub>LOWBAT</sub>              | Low battery detect voltage, VBATSEL=0x0           | 1.8 | 1.9     | 2.0              | V    |
|                                  | Low battery detect voltage, VBATSEL=0x1           | 2.0 | 2.1     | 2.2              | V    |
|                                  | Low battery detect voltage, VBATSEL=0x2           | 2.2 | 2.3     | 2.4              | V    |
|                                  | Low battery detect voltage, VBATSEL=0x3           | 2.4 | 2.5     | 2.6              | V    |

a. To ensure proper functionality, any voltage input higher than V<sub>BAT</sub> Max, must be connected through a diode.

b. For recommended V<sub>BAT</sub> RC circuit values, refer to the diagrams located in “Hibernation Clock Source” on page 524.

**Table 29-30. Hibernation Module Characteristics**

| Parameter No | Parameter                | Parameter Name   | Min | Nom  | Max | Unit                     |
|--------------|--------------------------|--|-----|--|-----|--------------------------|
| H1           | T <sub>WAKE</sub>        | $\overline{WAKE}$ assertion time   | 100 | -  | -   | ns                       |
| H2           | T <sub>WAKE_TO_HIB</sub> | $\overline{WAKE}$ assert to $\overline{HIB}$ desassert (wake up time)                                    | -   | -  | 1   | Hibernation clock period |
| H3           | T <sub>VDD_RAMP</sub>    | V <sub>DD</sub> ramp to 3.0 V  | -   | Depends on characteristics of power supply | -   | μs                       |
| H4           | T <sub>VDD_CODE</sub>    | V <sub>DD</sub> at 3.0 V to internal POR deassert; first instruction executes                            | -   | -  | 500 | μs                       |
| H5           | DC <sub>RTCCLK</sub>     | Duty cycle for RTCCLK output signal, when using a 32.768-kHz crystal                                     | 40  | -  | 60  | %                        |
|              |                          | Duty cycle for RTCCLK output signal, when using a 32.768-kHz external single-ended (bypass) clock source | 30  | -  | 70  | %                        |

**Table 29-31. Hibernation Module Tamper I/O Characteristics**

| Parameter         | Parameter Name  | Min                   | Nominal | Max      | Unit |
|-------------------|---|-----------------------|---------|----------|------|
| R <sub>TPU</sub>  | TMPR <sub>n</sub> pull-up resistor  | 3.5<br>-              | 4.4     | 5.2<br>- | MΩ   |
| T <sub>SP</sub>   | TMPR <sub>n</sub> pulse width with short glitch filter                          | 62                    | -       | -        | μs   |
| T <sub>LP</sub>   | TMPR <sub>n</sub> pulse width with long glitch filter                           | 94                    | -       | -        | ms   |
| T <sub>NMIS</sub> | TMPR <sub>n</sub> assertion to NMI (short glitch filter)                        | -                     | -       | 95       | μs   |
| T <sub>NMIL</sub> | TMPR <sub>n</sub> assertion to NMI (long glitch filter)                         | -                     | -       | 94       | ms   |
| V <sub>IH</sub>   | TMPR <sub>n</sub> high-level input voltage when operating from V <sub>BAT</sub> | V <sub>BAT</sub> *0.8 | -       | -        | V    |

Figure 29-15. Hibernation Module Timing

## 29.12 Flash Memory

**Table 29-32. Flash Memory Characteristics**

| Parameter            | Parameter Name  | Min     | Nom | Max  | Unit   |
|----------------------|---|---------|-----|------|--------|
| PE <sub>CYC</sub>    | Number of program/erase cycles <sup>a</sup>   | 100,000 | -   | -    | cycles |
| T <sub>RET</sub>     | Data retention with 100% power-on hours at T <sub>J</sub> =85°C   | 20      | -   | -    | years  |
| T <sub>RET_EXT</sub> | Data retention with 10% power-on hours at T <sub>J</sub> =125°C and 90% power-on hours at T <sub>J</sub> =100°C | 11      | -   | -    | years  |
| T <sub>PROG64</sub>  | Program time for double-word-aligned (64 bits) data <sup>b</sup>  | 30      | 100 | 300  | μs     |
| T <sub>ERASE</sub>   | Page erase time, <1k cycles   | -       | 8   | 15   | ms     |
|                      | Page erase time, 10k cycles   | -       | 15  | 40   | ms     |
|                      | Page erase time, 100k cycles  | -       | 75  | 500  | ms     |
| T <sub>ME</sub>      | Mass erase time, <1k cycles   | -       | 10  | 25   | ms     |
|                      | Mass erase time, 10k cycles   | -       | 20  | 70   | ms     |
|                      | Mass erase time, 100k cycles  | -       | 300 | 2500 | ms     |

a. A program/erase cycle is defined as switching the bits from 1-> 0 -> 1.

b. If programming fewer than 64 bits of data, the programming time is the same. For example, if only 32 bits of data need to be programmed, the other 32 bits are masked off.

## 29.13 EEPROM

**Table 29-33. EEPROM Characteristics<sup>a</sup>**

| Parameter                       | Parameter Name  | Min     | Nom           | Max       | Unit          |
|---------------------------------|---|---------|---------------|-----------|---------------|
| EPE <sub>CYC</sub> <sup>b</sup> | Number of mass program/erase cycles of a single word <sup>c</sup>   | 500,000 | -             | -         | cycles        |
| ET <sub>RET</sub>               | Data retention with 100% power-on hours at T <sub>J</sub> =85°C   | 20      | -             | -         | years         |
| ET <sub>RET_EXTEMP</sub>        | Data retention with 10% power-on hours at T <sub>J</sub> =125°C and 90% power-on hours at T <sub>J</sub> =100°C   | 11      | -             | -         | years         |

- a. Because the EEPROM operates as a background task and does not prevent the CPU from executing from Flash memory, the operation will complete within the maximum time specified provided the EEPROM operation is not stalled by a Flash memory program or erase operation.
- b. One word can be written more than 500K times, but these writes impact the endurance of the words in the meta-block that the word is within. Different words can be written such that any or all words can be written more than 500K times when write counts per word stay about the same. See the section called "Endurance" on page 609 for more information.
- c. A program/erase cycle is defined as switching the bits from 1-> 0 -> 1.
- d. The EWS field is programmed in the **MEMTIMO** register at Sysctl Offset 0x0C0.

## 29.14 Input/Output Pin Characteristics

**Note:** All GPIO signals are 3.3-V tolerant, except for PB1 (USB0VBUS) which is 5-V tolerant. See “Signal Description” on page 732 for more information on GPIO configuration.

Two types of pads are provided on the device:

- Fast GPIO pads: These pads provide variable, programmable drive strength and optimized voltage output levels.
- Slow GPIO pads: These pads provide 2-mA drive strength and are designed to be sensitive to voltage inputs. The following GPIOs port pins are designed with Slow GPIO Pads:
  - PJ1

**Note:** Port pins  $PL6$  and  $PL7$  operate as Fast GPIO pads, but have 4-mA drive capability only. GPIO register controls for drive strength, slew rate and open drain have no effect on these pins. The registers which have no effect are as follows: **GPIODR2R**, **GPIODR4R**, **GPIODR8R**, **GPIODR12R**, **GPIOSLR**, and **GPIOODR**.

**Note:** Port pins  $PM[7:4]$  operate as Fast GPIO pads but support only 2-, 4-, 6-, and 8-mA drive capability. 10- and 12-mA drive are not supported. All standard GPIO register controls, except for the **GPIODR12R** register, apply to these port pins.

**Table 29-34. Fast GPIO Module Characteristics**<sup>abcd</sup>

| Parameter       | Parameter Name  | Min  | Nom  | Max   | Unit       |
|-----------------|---|------|------|-------|------------|
| $C_{LGPIO}$     | Capacitive loading for measurements given in this table <sup>e</sup>  | -    | -    | 50    | pF         |
| $R_{GPIOU}$     | Fast GPIO internal pull-up resistor <sup>f</sup>  | 12.1 | 16.0 | 20.2  | k $\Omega$ |
| $R_{GPIOU4MA}$  | Fast GPIO $PL6$ and $PL7$ (4-mA only) pull-up resistor  | 25   | -    | 40    | k $\Omega$ |
| $R_{GPIOPD}$    | Fast GPIO internal pull-down resistor <sup>f</sup>  | 13.0 | 20.5 | 35.5  | k $\Omega$ |
| $R_{GPIOPD4MA}$ | Fast GPIO $PL6$ and $PL7$ (4-mA only) pull-down resistor  | 10   | 14.3 | 17    | k $\Omega$ |
| $I_{LKG+}$      | Fast GPIO input leakage current, $0V \leq V_{IN} \leq V_{DD}$ GPIO pins <sup>g</sup>                                      | -    | -    | 400   | nA         |
|                 | Fast GPIO input leakage current, $0V < V_{IN} \leq V_{DD}$ , Fast GPIO pins configured as ADC or analog comparator inputs | -    | -    | 400   | nA         |
| $I_{INJ-}$      | DC injection current, $V_{IN} \leq 0V$  | -    | -    | 60    | $\mu$ A    |
| $I_{MAXINJ-}$   | Max negative injection if not voltage protected <sup>d</sup>  | -    | -    | -0.5  | mA         |
| $T_{GPIOR}$     | Fast GPIO rise time, 2-mA drive <sup>h</sup>  | -    | 7.85 | 11.73 | ns         |
|                 | Fast GPIO rise time, 4-mA drive <sup>h</sup>  |      | 4.15 | 6.35  | ns         |
|                 | Fast GPIO rise time, 8-mA drive <sup>h</sup>  |      | 2.33 | 3.73  | ns         |
|                 | Fast GPIO rise time, 8-mA drive with slew rate control <sup>h</sup>   |      | 3.77 | 5.76  | ns         |
|                 | Fast GPIO rise time, 10-mA drive <sup>h</sup>   |      | 1.98 | 3.22  | ns         |
|                 | Fast GPIO rise time, 12-mA drive <sup>h</sup>   |      | 1.75 | 2.9   | ns         |

**Table 29-34. Fast GPIO Module Characteristics (continued)**

| Parameter   | Parameter Name  | Min | Nom  | Max  | Unit |
|-------------|---|-----|------|------|------|
| $T_{GPIOF}$ | Fast GPIO fall time, 2-mA drive <sup>i</sup>                        | -   | 10.3 | 16.5 | ns   |
|             | Fast GPIO fall time, 4-mA drive <sup>i</sup>                        |     | 5.15 | 8.29 | ns   |
|             | Fast GPIO fall time, 8-mA drive <sup>i</sup>                        |     | 2.58 | 4.16 | ns   |
|             | Fast GPIO fall time, 8-mA drive with slew rate control <sup>i</sup> |     | 3.54 | 5.55 | ns   |
|             | Fast GPIO fall time, 10-mA drive <sup>i</sup>                       |     | 2.07 | 3.34 | ns   |
|             | Fast GPIO fall time, 12-mA drive <sup>i</sup>                       |     | 1.73 | 2.78 | ns   |

- a.  $V_{DD}$  must be within the range specified in Table 29-6 on page 1707.
- b. Leakage and Injection current characteristics specified in this table also apply to XOSC0 and XOSC1 inputs.
- c. Note that for the ADC's external reference inputs, care must be taken to avoid a current limiting resistor (refer to  $I_{VREF}$  spec in Table 29-44 on page 1748)
- d. I/O pads should be protected if at any point the IO voltage has a possibility of going outside the limits shown in the table. If the part is unpowered, the IO pad Voltage or Current must be limited (as shown in this table) to avoid powering the part through the IO pad, causing potential irreversible damage.
- e. Refer to individual peripheral sections for specific loading information.
- f. This value includes all GPIO except for port pins  $PL6$  and  $PL7$ .
- g. The leakage current is measured with  $V_{IN}$  applied to the corresponding pin(s). The leakage of digital port pins is measured individually. The port pin is configured as an input and the pull-up/pull-down resistor is disabled.
- h. Time measured from 20% to 80% of  $V_{DD}$ .
- i. Time measured from 80% to 20% of  $V_{DD}$ .

**Table 29-35. Slow GPIO Module Characteristics<sup>abc</sup>**

| Parameter    | Parameter Name  | Min  | Nom  | Max  | Unit       |
|--------------|---|------|------|------|------------|
| $C_{LGPIO}$  | Capacitive loading for measurements given in this table <sup>d</sup>  | -    | -    | 50   | pF         |
| $R_{GPIOPU}$ | Slow GPIO internal pull-up resistor   | 13.8 | 20.0 | 31.4 | k $\Omega$ |
| $R_{GPIOPD}$ | Slow GPIO internal pull-down resistor   | 13.0 | 20.5 | 35.5 | k $\Omega$ |
| $I_{LKG+}$   | Slow GPIO input leakage current, $0 V \leq V_{IN} \leq V_{DD}$ , GPIO pins <sup>e</sup>                               | -    | -    | 3.25 | nA         |
|              | Slow GPIO input leakage current, $0 V < V_{IN} \leq V_{DD}$ , GPIO pins configured as ADC or analog comparator inputs | -    | -    | 3.25 | nA         |
| $I_{INJ-}$   | DC injection current, $V_{IN} \leq 0 V$   | -    | -    | 3.42 | $\mu A$    |
| $T_{GPIOR}$  | Slow GPIO rise time, 2-mA drive <sup>f</sup>  | -    | 19.3 | 29.8 | ns         |
| $T_{GPIOF}$  | Slow GPIO fall time, 2-mA drive <sup>g</sup>  | -    | 12.8 | 21.1 | ns         |

- a.  $V_{DD}$  must be within the range specified in Table 29-6 on page 1707.
- b.  $V_{IN}$  must be within the range specified in Table 29-1 on page 1705. Leakage current outside of this maximum voltage is not guaranteed and can result in permanent damage of the device.
- c. To avoid potential damage to the part, either the voltage or current on the non-Power, non-WAKE input/outputs should be limited externally as shown in this table.
- d. Refer to individual peripheral sections for specific loading information.
- e. The leakage current is measured with  $V_{IN}$  applied to the corresponding pin(s). The leakage of digital port pins is measured individually. The port pin is configured as an input and the pull-up/pull-down resistor is disabled.
- f. Time measured from 20% to 80% of  $V_{DD}$ .
- g. Time measured from 80% to 20% of  $V_{DD}$ .

### 29.14.1 Types of I/O Pins and ESD Protection

**Caution** – All device I/Os pins, except for PB1, are NOT 5V tolerant; voltages in excess of the limits shown in Table 29-6 on page 1707 can permanently damage the device. PB1 is used for the USB's USB0VBUS signal, which requires a 5-V input.

#### 29.14.1.1 Hibernate $\overline{\text{WAKE}}$ pin

The Hibernate  $\overline{\text{WAKE}}$  pin uses ESD protection, similar to the one shown in Figure 29-16 on page 1738. This ESD protection prevents a direct path between this pad and any power supply rails in the device. The  $\overline{\text{WAKE}}$  pad input voltage should be kept inside the maximum ratings specified in Table 29-1 on page 1705 to ensure current leakage and current injections are within acceptable range. Current leakages and current injection for these pins are specified in Table 29-36 on page 1738.

**Figure 29-16. ESD Protection**

**Table 29-36. Pad Voltage/Current Characteristics for Hibernate  $\overline{\text{WAKE}}$  Pin<sup>ab</sup>**

| Parameter         | Parameter Name   | Min | Nom | Max  | Unit          |
|-------------------|--|-----|-----|------|---------------|
| $I_{\text{LKG}+}$ | Positive IO leakage for $V_{\text{DD}} \leq V_{\text{IN}} \leq V_{\text{BAT}} + 0.3\text{V}$ | -   | -   | 300  | nA            |
| $I_{\text{LKG}-}$ | Negative IO leakage for $-0.3\text{V} \leq V_{\text{IN}} \leq 0\text{V}^{\text{c}}$          | -   | -   | 43.3 | $\mu\text{A}$ |
| $I_{\text{INJ}+}$ | Max positive injection if not voltage protected <sup>d</sup>                                 | -   | -   | 2    | mA            |
| $I_{\text{INJ}-}$ | Max negative injection if not voltage protected <sup>d</sup>                                 | -   | -   | -0.5 | mA            |

a.  $V_{\text{IN}}$  must be within the range specified in Table 29-1 on page 1705. Leakage current outside of this maximum voltage is not guaranteed and can result in permanent damage of the device.

b.  $V_{\text{DD}}$  must be within the range specified in Table 29-6 on page 1707.

c. Leakage outside the minimum range (-0.3V) is unbounded and must be limited to  $I_{\text{INJ}-}$  using an external resistor.

d. If the I/O pad is not voltage limited, it should be current limited (to  $I_{\text{INJ}+}$  and  $I_{\text{INJ}-}$ ) if there is any possibility of the pad voltage exceeding the  $V_{\text{IO}}$  limits (including transient behavior during supply ramp up, or at any time when the part is unpowered).

#### 29.14.1.2 Non-Power I/O Pins

Most non-power I/Os (with the exception of the I/O pad for Hibernate  $\overline{\text{WAKE}}$  input) have ESD protection as shown in Figure 29-17 on page 1739.

These I/Os have an ESD clamp to ground and a diode connection to the corresponding power supply rail. The voltage and current of these I/Os should follow the specifications in Table 29-37 on page 1739 to prevent potential damage to the device. In addition, it is recommended that the ADC external reference specifications in Table 29-44 on page 1748 be adhered to prevent any gain error.

Figure 29-17. ESD Protection for Non-Power Pins (Except  $\overline{\text{WAKE}}$  Signal)Table 29-37. Non-Power I/O Pad Voltage/Current Characteristics<sup>abc</sup>

| Parameter  | Parameter Name   | Min  | Nom      | Max          | Unit          |
|------------|--|------|----------|--------------|---------------|
| $V_{IO}^d$ | IO pad voltage limits if voltage protected                             | -0.3 | $V_{DD}$ | $V_{DD}+0.3$ | V             |
| $I_{LKG+}$ | Positive IO leakage for $V_{DD} \leq V_{IN} \leq V_{IO} \text{ MAX}^e$ | -    | -        | 400          | nA            |
| $I_{LKG-}$ | Negative IO leakage for $V_{IO} \text{ MIN} \leq V_{IN} \leq 0V^e$     | -    | -        | 60           | $\mu\text{A}$ |
| $I_{INJ+}$ | Max positive injection if not voltage protected <sup>f</sup>           | -    | -        | 2            | mA            |
| $I_{INJ-}$ | Max negative injection if not voltage protected <sup>f</sup>           | -    | -        | -0.5         | mA            |

- To avoid potential damage to the part, either the voltage or current on the non-Power, non- $\overline{\text{WAKE}}$  input/outputs should be limited externally as shown in this table.
- Note that for the ADC's external reference inputs, care must be taken to avoid a current limiting resistor (refer to IVREF spec in Table 29-44 on page 1748)
- I/O pads should be protected if at any point the IO voltage has a possibility of going outside the limits shown in the table. If the part is unpowered, the IO pad Voltage or Current must be limited (as shown in this table) to avoid powering the part through the IO pad, causing potential irreversible damage.
- The Hibernate  $\overline{\text{XOSC}}$  pins are non-failsafe and should follow the limits for  $V_{IO}$  with respect to both  $V_{DD}$  and  $V_{BAT}$ . Thus  $V_{IO}$  for the HIB  $\overline{\text{XOSC}}$  pins should also fall within a MIN of -0.3 and a MAX of  $V_{BAT} + 0.3$ .
- MIN and MAX leakage current for the case when the I/O is voltage protected to  $V_{IO} \text{ Min}$  or  $V_{IO} \text{ Max}$ .
- If the I/O pad is not voltage limited, it should be current limited (to  $I_{INJ+}$  and  $I_{INJ-}$ ) if there is any possibility of the pad voltage exceeding the  $V_{IO}$  limits (including transient behavior during supply ramp up, or at any time when the part is unpowered).

## 29.15 External Peripheral Interface (EPI)

**Table 29-38. EPI Interface Load Conditions**

| Signals                               | Load Value ( $C_L$ ) |
|---------------------------------------|----------------------|
| EPI0S[35:0] SDRAM interface           | 30 pF                |
| EPI0S[35:0] General-Purpose interface |                      |
| EPI0S[35:0] Host-Bus interface        |                      |
| EPI0S[35:0] PSRAM interface           | 40 pF                |

When the EPI module is in SDRAM mode, EPI CLK must be configured to 12 mA. The EPI data bus can be configured to 8 mA. Table 29-39 on page 1740 shows the rise and fall times in SDRAM mode. When the EPI module is in Host-Bus or General-Purpose mode, the values in “Input/Output Pin Characteristics” on page 1736 should be used.

**Table 29-39. EPI SDRAM Characteristics**

| Parameter    | Parameter Name                               | Condition                  | Min | Nom | Max | Unit |
|--------------|--|----------------------------|-----|-----|-----|------|
| $T_{SDRAMR}$ | EPI Rise Time (from 20% to 80% of $V_{DD}$ ) | 12-mA drive, $C_L = 30$ pF | -   | 2   | 3   | ns   |
| $T_{SDRAMF}$ | EPI Fall Time (from 80% to 20% of $V_{DD}$ ) | 12-mA drive, $C_L = 30$ pF | -   | 2   | 3   | ns   |

**Table 29-40. EPI SDRAM Interface Characteristics<sup>a</sup>**

| Parameter No | Parameter | Parameter Name         | Min   | Nom | Max | Unit    |
|--------------|-----------|------------------------|-------|-----|-----|---------|
| E1           | $T_{CK}$  | SDRAM Clock period     | 16.67 | -   | -   | ns      |
| E2           | $T_{CH}$  | SDRAM Clock high time  | 8.33  | -   | -   | ns      |
| E3           | $T_{CL}$  | SDRAM Clock low time   | 8.33  | -   | -   | ns      |
| E4           | $T_{COV}$ | CLK to output valid    | -     | -   | 4   | ns      |
| E5           | $T_{COI}$ | CLK to output invalid  | -     | -   | 4   | ns      |
| E6           | $T_{COT}$ | CLK to output tristate | -     | -   | 4   | ns      |
| E7           | $T_S$     | Input set up to CLK    | 8.5   | -   | -   | ns      |
| E8           | $T_H$     | CLK to input hold      | 0     | -   | -   | ns      |
| E9           | $T_{PU}$  | Power-up time          | 100   | -   | -   | $\mu$ s |
| E10          | $T_{RP}$  | Precharge all banks    | 20    | -   | -   | ns      |
| E11          | $T_{RFC}$ | Auto refresh           | 66    | -   | -   | ns      |
| E12          | $T_{MRD}$ | Program mode register  | 2     | -   | -   | EPI CLK |

a. The EPI SDRAM interface must use 12-mA drive.

| $E_{TSENS}$                                      | Temperature sensor accuracy at: <sup>z</sup><br>-40°C to 85 °C ambient (industrial temperature part)<br>-40°C to 105 °C ambient (extended temperature part) | -   | -     | ±5                     | °C    |

a. Values are at  $V_{REF+} = 3.3V$ ,  $F_{ADC} = 16$  MHz unless otherwise noted.

b. Best design practices suggest that static or quiet digital I/O signals be configured adjacent to sensitive analog inputs to reduce capacitive coupling and cross talk. Unexpected results can occur if a switching digital I/O is placed adjacent to an ADC input channel or voltage reference input. In addition, analog signals configured adjacent to ADC input channels or reference inputs must meet the  $R_{ADC}$  equivalent input resistance given in this table and must be band-limited to 100 kHz or lower.

c. Two capacitors in parallel. Note that these capacitors should be as close to the die as possible.

d. Assumes external filtering network between VREF+ and VREF- as shown in Figure 29-28 on page 1753. External reference noise level must be under 12bit (-74 dB) of Full Scale input, over input bandwidth, measured at VREF+ - VREF-.

e. Internal reference is connected directly between  $V_{DDA}$  and GNDA ( $V_{REFi} = V_{DDA} - GNDA$ ). In this mode,  $E_O$ ,  $E_G$ ,  $E_T$ , and dynamic specifications are adversely affected due to internal voltage drop and noise on  $V_{DDA}$  and GNDA. Internal reference voltage is selected when  $V_{REF}$  field in the **ADCCTL** register is 0x0.

- f.  $V_{ADCIN} = V_{INP} - V_{INN}$
- g. With signal common mode as  $V_{DDA}/2$ .
- h. With signal common mode as  $(V_{REF+} + V_{REF-})/2$ .
- i. This parameter is defined as the average of the differential inputs.
- j. As shown in Figure 29-29 on page 1753,  $R_{ADC}$  is the total equivalent resistance in the input line all the way up to the sampling node at the input of the ADC.
- k. See "System Clock Specification with ADC Operation" on page 1729 for full ADC clock frequency specification.
- l. ADC conversion time ( $T_c$ ) includes the ADC sample time ( $T_s$ ).
- m. Low noise environment is assumed in order to obtain values close to spec. Board must have good ground isolation between analog and digital grounds, a clean reference voltage is assumed, and input signal must be bandlimited to Nyquist bandwidth. No anti-aliasing filter is provided internally.
- n. ADC static measurements taken by averaging over several samples. At least 20-sample averaging is assumed to obtain expected typical or maximum spec values.
- o. 12-bit DNL
- p. Gain error is measured at max code after compensating for offset. Gain error is equivalent to "Full Scale Error." It can be given in % of slope error, or in LSB, as done here.
- q. Total Unadjusted Error is the maximum error at any one code versus the ideal ADC curve. It includes all other errors (offset error, gain error and INL) at any given ADC code.
- r. A low noise environment is assumed in order to obtain values close to spec. The board must have good ground isolation between analog and digital grounds and a clean reference voltage. The input signal must be band-limited to Nyquist bandwidth. No anti-aliasing filter is provided internally.
- s. ADC dynamic characteristics are measured using low-noise board design, with low-noise reference voltage ( $< -74$ dB noise level in signal BW) and low-noise analog supply voltage. Board noise and ground bouncing couple into the ADC and affect dynamic characteristics. Clean external reference must be used to achieve shown specs.
- t. Differential signal with correct common mode, applied between two ADC inputs.
- u. SDR = -THD in dB.
- v. For higher frequency inputs, degradation in SDR should be expected.
- w. SNDR =  $S/(N+D)$  = SINAD (in dB)
- x. Effective number of bits (ENOB) can be calculated from SNDR:  $ENOB = (SNDR - 1.76) / 6.02$ .
- y. Single ended inputs are more sensitive to board and trace noise than differential inputs; SNR and SNDR measurements on single-ended inputs are highly dependent on how clean the test set-up is. If the input signal is not well-isolated on the board, higher noise than specified could potentially be seen at the ADC output.
- z. Note that this parameter does not include ADC error.

**Table 29-45. ADC Electrical Characteristics for ADC at 2 Msps<sup>ab</sup>**

| Parameter                        | Parameter Name  | Min   | Nom                      | Max       | Unit    |

| DYNAMIC CHARACTERISTICS <sup>rs</sup>                          |   |                            |            |   |            |
| $SNR_D$  | Signal-to-noise-ratio, Differential input, $V_{ADCIN}$ : -20dB FS, 1KHz <sup>t</sup>      | 68                         | 72         | -   | dB         |
| $SDR_D$  | Signal-to-distortion ratio, Differential input, $V_{ADCIN}$ : -3dB FS, 1KHz <sup>uv</sup> | 70                         | 75         | -   | dB         |

Table 29-45. ADC Electrical Characteristics for ADC at 2 Msps (continued)

| Parameter         | Parameter Name  | Min | Nom | Max | Unit |
|-------------------|---|-----|-----|-----|------|
| SNDR <sub>D</sub> | Signal-to-Noise+Distortion ratio, Differential input, V <sub>ADCIN</sub> : -3dB FS, 1KHz <sup>twx</sup> | 65  | 70  | -   | dB   |
| SNR <sub>S</sub>  | Signal-to-noise-ratio, Single-ended input, V <sub>ADCIN</sub> : -20dB FS, 1KHz <sup>y</sup>             | 58  | 65  | -   | dB   |
| SDR <sub>S</sub>  | Signal-to-distortion ratio, Single-ended input, V <sub>ADCIN</sub> : -3dB FS, 1KHz <sup>uv</sup>        | 68  | 72  | -   | dB   |
| SNDR <sub>S</sub> | Signal-to-Noise+Distortion ratio, Single-ended input, V <sub>ADCIN</sub> : -3dB FS, 1KHz <sup>ywx</sup> | 58  | 63  | -   | dB   |

- a. Values are at V<sub>REF+</sub> = 3.3V, F<sub>ADC</sub> = 32 MHz unless otherwise noted.
- b. Best design practices suggest that static or quiet digital I/O signals be configured adjacent to sensitive analog inputs to reduce capacitive coupling and cross talk. Unexpected results can occur if a switching digital I/O is placed adjacent to an ADC input channel or voltage reference input. In addition, analog signals configured adjacent to ADC input channels or reference inputs must meet the R<sub>ADC</sub> equivalent input resistance given in this table and must be band-limited to 100 kHz or lower.
- c. Two capacitors in parallel. Note that these capacitors should be as close to the die as possible.
- d. Assumes external filtering network between VREFA+ and VREFA- as shown in Figure 29-28 on page 1753. External reference noise level must be under 12bit (-74 dB) of Full Scale input, over input bandwidth, measured at VREFA+ - VREFA-.
- e. Internal reference is connected directly between V<sub>DDA</sub> and GNDA (VREFi = V<sub>DDA</sub> - GNDA). In this mode, E<sub>O</sub>, E<sub>G</sub>, E<sub>T</sub>, and dynamic specifications are adversely affected due to internal voltage drop and noise on V<sub>DDA</sub> and GNDA. Internal reference voltage is selected when VREF field in the **ADCCTL** register is 0x0.
- f. V<sub>ADCIN</sub> = V<sub>INP</sub> - V<sub>INN</sub>
- g. With signal common mode as V<sub>DDA</sub>/2.
- h. With signal common mode as (V<sub>REF+</sub> + V<sub>REF-</sub>)/2.
- i. This parameter is defined as the average of the differential inputs.
- j. As shown in Figure 29-29 on page 1753, R<sub>ADC</sub> is the total equivalent resistance in the input line all the way up to the sampling node at the input of the ADC.
- k. See "System Clock Specification with ADC Operation" on page 1729 for full ADC clock frequency specification.
- l. ADC conversion time (T<sub>c</sub>) includes the ADC sample time (T<sub>s</sub>).
- m. Low noise environment is assumed in order to obtain values close to spec. Board must have good ground isolation between analog and digital grounds, a clean reference voltage is assumed, and input signal must be bandlimited to Nyquist bandwidth. No anti-aliasing filter is provided internally.
- n. ADC static measurements taken by averaging over several samples. At least 20-sample averaging is assumed to obtain expected typical or maximum spec values.
- o. 12-bit DNL
- p. Gain error is measured at max code after compensating for offset. Gain error is equivalent to "Full Scale Error." It can be given in % of slope error, or in LSB, as done here.
- q. Total Unadjusted Error is the maximum error at any one code versus the ideal ADC curve. It includes all other errors (offset error, gain error and INL) at any given ADC code.
- r. A low noise environment is assumed in order to obtain values close to spec. The board must have good ground isolation between analog and digital grounds and a clean reference voltage. The input signal must be band-limited to Nyquist bandwidth. No anti-aliasing filter is provided internally.
- s. ADC dynamic characteristics are measured using low-noise board design, with low-noise reference voltage (< -74dB noise level in signal BW) and low-noise analog supply voltage. Board noise and ground bouncing couple into the ADC and affect dynamic characteristics. Clean external reference must be used to achieve shown specs.
- t. Differential signal with correct common mode, applied between two ADC inputs.
- u. SDR = -THD in dB.
- v. For higher frequency inputs, degradation in SDR should be expected.
- w. SNDR = S/(N+D) = SINAD (in dB)
- x. Effective number of bits (ENOB) can be calculated from SNDR: ENOB = (SNDR - 1.76) / 6.02.

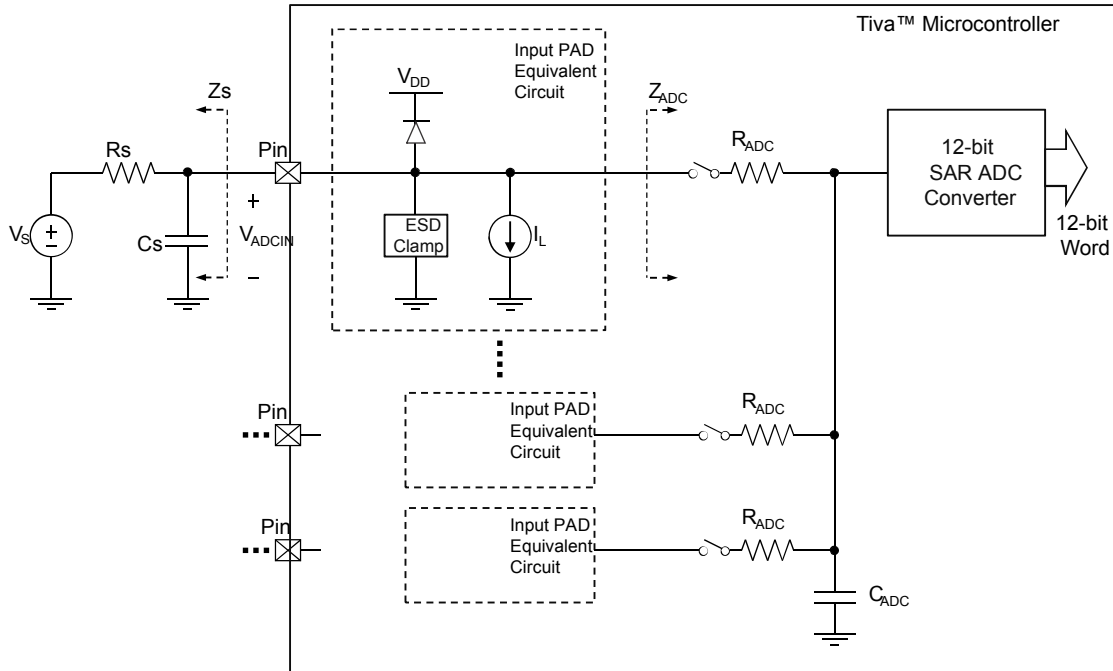

y. Single ended inputs are more sensitive to board and trace noise than differential inputs; SNR and SNDR measurements on single-ended inputs are highly dependent on how clean the test set-up is. If the input signal is not well-isolated on the board, higher noise than specified could potentially be seen at the ADC output.

## 29.17 Synchronous Serial Interface (SSI)

Table 29-46. SSI Characteristics

| Parameter No. | Parameter             | Parameter Name  | Min                | Nom | Max                | Unit |
|---------------|-----------------------|---|--------------------|-----|--------------------|------|
| S1            | T <sub>CLK_PER</sub>  | SSIClk cycle time, as master <sup>a</sup>                                       | 16.67              | -   | -                  | ns   |
|               |                       | SSIClk cycle time, as slave <sup>b</sup>  | 100                | -   | -                  | ns   |
| S2            | T <sub>CLK_HIGH</sub> | SSIClk high time, as master   | 8.33               | -   | -                  | ns   |
|               |                       | SSIClk high time, as slave  | 50                 | -   | -                  | ns   |
| S3            | T <sub>CLK_LOW</sub>  | SSIClk low time, as master  | 8.33               | -   | -                  | ns   |
|               |                       | SSIClk low time, as slave   | 50                 | -   | -                  | ns   |
| S4            | T <sub>CLKR</sub>     | SSIClk rise time <sup>c</sup>   | 1.25               | -   | -                  | ns   |
| S5            | T <sub>CLKF</sub>     | SSIClk fall time <sup>c</sup>   | 1.25               | -   | -                  | ns   |
| S6            | T <sub>TXDMOV</sub>   | Master Mode: Master Tx Data Output (to slave)<br>Valid Time from edge of SSIClk | -                  | -   | 4.00               | ns   |
| S7            | T <sub>TXDMOH</sub>   | Master Mode: Master Tx Data Output (to slave)<br>Hold Time after next SSIClk    | 0.60               | -   | -                  | ns   |
| S8            | T <sub>RXDMS</sub>    | Master Mode: Master Rx Data In (from slave)<br>setup time                       | 7.89               | -   | -                  | ns   |
| S9            | T <sub>RXDMH</sub>    | Master Mode: Master Rx Data In (from slave) hold<br>time                        | 0                  | -   | -                  | ns   |
| S10           | T <sub>TXDSOV</sub>   | Slave Mode: Master Tx Data Output (to Master)<br>Valid Time from edge of SSIClk | -                  | -   | 47.60 <sup>d</sup> | ns   |
| S11           | T <sub>TXDSOH</sub>   | Slave Mode: Slave Tx Data Output (to Master)<br>Hold Time from next SSIClk      | 37.4 <sup>e</sup>  | -   | -                  | ns   |
| S13           | T <sub>RXDSSU</sub>   | Slave Mode: Rx Data In (from master) setup time                                 | 0                  | -   | -                  | ns   |
| S14           | T <sub>RXDSSH</sub>   | Slave Mode: Rx Data In (from master) hold time                                  | 37.03 <sup>f</sup> | -   | -                  | ns   |

a. In master mode, the system clock must be at least twice as fast as the SSIClk.

b. In slave mode, the system clock must be at least 12 times faster than the SSIClk.

c. Note that the delays shown are using 12-mA drive strength.

d. This MAX value is for the minimum slave mode T<sub>SYSClk</sub> period (8.33 ns). To find the MAX T<sub>TXDSOV</sub> value for a larger T<sub>SYSClk</sub>, use the equation: 4\*T<sub>SYSClk</sub>+14.25.

e. This MIN value is for the minimum slave mode T<sub>SYSClk</sub> (8.33 ns). To find the MIN T<sub>TXDSOH</sub> value for a larger T<sub>SYSClk</sub>, use the equation: 4\*T<sub>SYSClk</sub>+4.08.

f. This MIN value is for the minimum slave mode T<sub>SYSClk</sub> (8.33 ns). To find the MIN T<sub>TXDSSH</sub> value for a larger T<sub>SYSClk</sub>, use the equation: 4\*T<sub>SYSClk</sub>+3.70.

| I5 <sup>c</sup> | T <sub>SFT</sub>  | I <sup>2</sup> C <sub>SCL</sub> /I <sup>2</sup> C <sub>SDA</sub> fall time (V <sub>IH</sub> = 2.4 V to V <sub>IL</sub> = 0.5 V) | -   | 9                   | 10           | ns            |
| I6 <sup>a</sup> | T <sub>HT</sub>   | Clock High time   | 24  | -                   | -            | system clocks |
| I7              | T <sub>DS</sub>   | Data setup time   | 18  | -                   | -            | system clocks |
| I8 <sup>a</sup> | T <sub>SCSR</sub> | Start condition setup time (for repeated start condition only)  | 36  | -                   | -            | system clocks |
| I9 <sup>a</sup> | T <sub>SCS</sub>  | Stop condition setup time   | 24  | -                   | -            | system clocks |
| I10             | T <sub>DV</sub>   | Data Valid (slave)  | -   | 2                   | -            | system clocks |
|                 |                   | Data Valid (master)   | -   | (6 * (1 + TPR)) + 1 | -            | system clocks |

- a. Values depend on the value programmed into the TPR bit in the I<sup>2</sup>C Master Timer Period (I2CMTPR) register; a TPR programmed for the maximum I<sup>2</sup>C<sub>SCL</sub> frequency (TPR=0x2) results in a minimum output timing as shown in the table above. The I<sup>2</sup>C interface is designed to scale the actual data transition time to move it to the middle of the I<sup>2</sup>C<sub>SCL</sub> Low period. The actual position is affected by the value programmed into the TPR; however, the numbers given in the above values are minimum values.
- b. Because I<sup>2</sup>C<sub>SCL</sub> and I<sup>2</sup>C<sub>SDA</sub> operate as open-drain-type signals, which the controller can only actively drive low, the time I<sup>2</sup>C<sub>SCL</sub> or I<sup>2</sup>C<sub>SDA</sub> takes to reach a high level depends on external signal capacitance and pull-up resistor values.
- c. Specified at a nominal 50 pF load.

Figure 29-33. I<sup>2</sup>C Timing

## 29.19 Universal Serial Bus (USB) Controller

The Tiva™ C Series USB controller electrical specifications are compliant with the *Universal Serial Bus Specification Rev. 2.0* (full-speed and low-speed support) and the *On-The-Go Supplement to the USB 2.0 Specification Rev. 1.0*. Some components of the USB system are integrated within the TM4C129CNCZAD microcontroller and specific to the Tiva™ C Series microcontroller design.

**Note:** GPIO pin, PB1, which can be configured as the USB0VBUS signal, is the only pin which is 5-V tolerant on the device.

**Table 29-49. ULPI Interface Timing**

| Parameter No.  | Parameter        | Parameter Name                           | Min | Nom | Max  | Unit |
|--|------------------|--|-----|-----|------|------|
| Timings with respect to external clock source input to USB0CLK |                  |  |     |     |      |      |

## 29.20 Analog Comparator

**Table 29-50. Analog Comparator Characteristics<sup>ab</sup>**

| Parameter            | Parameter Name                                | Min  | Nom      | Max        | Unit    |
|----------------------|---|------|----------|------------|---------|
| $V_{INP}, V_{INN}^c$ | Input voltage range                           | GNDA | -        | $V_{DDA}$  | V       |
| $V_{CM}$             | Input common mode voltage range               | GNDA | -        | $V_{DDA}$  | V       |
| $V_{OS}$             | Input offset voltage                          | -    | $\pm 10$ | $\pm 50^d$ | mV      |
| $I_{INP}, I_{INN}$   | Input leakage current over full voltage range | -    | -        | 2.0        | $\mu A$ |
| $C_{MRR}$            | Common mode rejection ratio                   | -    | 50       | -          | dB      |
| $T_{RT}$             | Response time                                 | -    | -        | $1.0^e$    | $\mu s$ |
| $T_{MC}$             | Comparator mode change to Output Valid        | -    | -        | 10         | $\mu s$ |

- a. Best design practices suggest that static or quiet digital I/O signals be configured adjacent to sensitive analog inputs to reduce capacitive coupling and cross talk.
- b. To achieve best analog results, the source resistance driving the analog inputs,  $V_{INP}$  and  $V_{INN}$ , should be kept low.
- c. The external voltage inputs to the Analog Comparator are designed to be highly sensitive and can be affected by external noise on the board. For this reason,  $V_{INP}$  and  $V_{INN}$  must be set to different voltage levels during idle states to ensure the analog comparator triggers are not enabled. If an internal voltage reference is used, it should be set to a mid-supply level. When operating in Sleep/Deep-Sleep modes, the Analog Comparator module should be disabled or the external voltage inputs set to different levels (greater than the input offset voltage) to achieve minimum current draw.
- d. Measured at  $V_{REF}=100$  mV.
- e. Measured at external  $V_{REF}=100$  mV, input signal switching from 75 mV to 125 mV.

**Table 29-51. Analog Comparator Voltage Reference Characteristics**

| Parameter | Parameter Name               | Min | Nom             | Max            | Unit |
|-----------|------------------------------|-----|-----------------|----------------|------|
| $R_{HR}$  | Resolution in high range     | -   | $V_{DDA}/29.4$  | -              | V    |
| $R_{LR}$  | Resolution in low range      | -   | $V_{DDA}/22.12$ | -              | V    |
| $A_{HR}$  | Absolute accuracy high range | -   | -               | $\pm R_{HR}/2$ | V    |
| $A_{LR}$  | Absolute accuracy low range  | -   | -               | $\pm R_{LR}/2$ | V    |

## 29.21 Pulse-Width Modulator (PWM)

**Table 29-54. PWM Timing Characteristics**

| Parameter    | Parameter Name                                     | Min | Nom | Max                | Unit              |
|--------------|--|-----|-----|--------------------|-------------------|
| $T_{FLTW}$   | Minimum Fault Pulse Width                          | 2   | -   | -                  | PWM clock periods |
| $T_{FLTMAX}$ | $MnFAULTn$ Assertion to PWM Inactive <sup>a</sup>  | -   | -   | 24 + (1 PWM clock) | ns                |
| $T_{FLTMIN}$ | $MnFAULTn$ De-Assertion to PWM Active <sup>b</sup> | 5   | -   | -                  | ns                |

a. This parameter value can vary depending on the PWM clock frequency which is controlled by the System Clock and a programmable divider field in the **PWMCC** register.

b. The latch and minimum fault period functions that can be enabled in the **PWMnCTL** register can change the timing of this parameter.

## 29.22 Current Consumption

Table 29-56 on page 1766 shows the amount of current consumption that specific peripherals contribute to the Run mode current consumption numbers shown in Table 29-55 on page 1763. If these peripherals are not powered, then the peripheral current consumption values can be subtracted from the Run mode numbers displayed in Table 29-55 on page 1763.

**Table 29-55. Current Consumption<sup>ab</sup>**

| Parameter  | Parameter Name             | Conditions  | System Clock  |                    | Nom   |      |      |                    | Max   |                    | Unit |

- a. Total current in RUN, SLEEP and DEEPSLEEP modes is the sum of I<sub>DD</sub> and I<sub>DDA</sub>.
- b. For Peripherals = All OFF, the clocks to all peripherals are turned off and the peripherals are powered down, if capable (see the section called "Peripheral Power Control" on page 244).
- c. Applicable to extended temperature devices only.
- d. Note that if the MOSC is the source of the Run-mode system clock and is powered down in Sleep mode, wake time is increased by T<sub>MOSC\_SETTLE</sub>.
- e. To achieve the lowest possible Deep-Sleep current, one or more wait states must be configured in the MEMTIMO register. If there are no wait states applied in Run mode, then lowest possible Deep-Sleep current is not achieved.
- f. See the section called "LDO Power Control" on page 245 for information on lowering the LDO voltage to 0.9 V.

**Table 29-56. Peripheral Current Consumption**

| Parameter   | Parameter Name                           | Conditions  | System Clock            | Nom | Units |
|-------------|--|---|-------------------------|-----|-------|
| $I_{DDUSB}$ | USB (including USB PHY) run mode current | $V_{DD} = 3.3\text{ V}$<br>$V_{DDA} = 3.3\text{ V}$ | 120 MHz (MOSC with PLL) | 4.0 | mA    |

## A Package Information

### A.1 Orderable Devices

The figure below defines the full set of orderable part numbers for the TM4C129x Series. See the Package Option Addendum for the complete list of valid orderable part numbers for the TM4C129CNCZAD microcontroller.

Figure A-1. Key to Part Numbers

### A.2 Device Nomenclature

To designate the stages in the product development cycle, TI assigns prefixes to the part numbers of all microcontroller (MCU) devices. Each Tiva™ C Series family member has one of two prefixes: XM4C or TM4C. These prefixes represent evolutionary stages of product development from engineering prototypes (XM4C) through fully qualified production devices (TM4C).

Device development evolutionary flow:

- XM4C — Experimental device that is not necessarily representative of the final device's electrical specifications and may not use production assembly flow.
- TM4C — Production version of the silicon die that is fully qualified.

XM4C devices are shipped against the following disclaimer:

"Developmental product is intended for internal evaluation purposes."

TM4C devices have been characterized fully, and the quality and reliability of the device have been demonstrated fully. TI's standard warranty applies.

Predictions show that prototype devices (XM4C) have a greater failure rate than the standard production devices. Texas Instruments recommends that these devices not be used in any production system because their expected end-use failure rate still is undefined. Only qualified production devices are to be used.

### A.3 Device Markings

The figure below shows an example of the Tiva™ microcontroller package symbolization.

This identifying number contains the following information:

- **Lines 1 and 5:** Internal tracking numbers
- **Lines 2 and 3:** Part number

For example, TM4C129X on the second line followed by NCZADI3 on the third line indicates orderable part number TM4C129XNCZADI3. Note that the first letter in the part number indicates the product status. A T indicates the part is fully qualified and released to production; an X indicates the part is experimental (pre-production) and requires a waiver. The silicon revision number is the last number in the part number, in this example, 3. The **DID0** register identifies the version of the microcontroller, as shown in the table below. Combined, the MAJOR and MINOR bit fields indicate the die revision and part revision numbers.

| MAJOR Bitfield Value | MINOR Bitfield Value | Die Revision | Part Revision |
|----------------------|----------------------|--------------|---------------|
| 0x0                  | 0x0                  | A0           | 1             |
| 0x0                  | 0x1                  | A1           | 2             |
| 0x0                  | 0x2                  | A2           | 3             |

- **Line 4:** Date code

The first two characters on the fourth line indicate the date code, followed by internal tracking numbers. The two-digit date code YM indicates the last digit of the year, then the month. For example, a 34 for the first two digits of the fourth line indicates a date code of April 2013.

## A.4 Packaging Diagram

Figure A-2. TM4C129CNCZAD 212-Ball BGA Package Diagram

### MECHANICAL DATA

ZAD (S-PBGA-N212)

PLASTIC BALL GRID ARRAY

- NOTES:
- All linear dimensions are in millimeters. Dimensioning and tolerancing per ASME Y14.5M-1994.
  - This drawing is subject to change without notice.
  - This is a Pb-free solder ball design.

**PACKAGING INFORMATION**

| Orderable Device | Status<br>(1) | Package Type | Package Drawing | Pins | Package Qty | Eco Plan<br>(2) | Lead finish/<br>Ball material<br>(6) | MSL Peak Temp<br>(3) | Op Temp (°C) | Device Marking<br>(4/5) | Samples   |

(1) The marketing status values are defined as follows:

**ACTIVE:** Product device recommended for new designs.

**LIFEBUY:** TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

**NRND:** Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

**PREVIEW:** Device has been announced but is not in production. Samples may or may not be available.

**OBsolete:** TI has discontinued the production of the device.

(2) **RoHS:** TI defines "RoHS" to mean semiconductor products that are compliant with the current EU RoHS requirements for all 10 RoHS substances, including the requirement that RoHS substance do not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, "RoHS" products are suitable for use in specified lead-free processes. TI may reference these types of products as "Pb-Free".

**RoHS Exempt:** TI defines "RoHS Exempt" to mean products that contain lead but are compliant with EU RoHS pursuant to a specific EU RoHS exemption.

**Green:** TI defines "Green" to mean the content of Chlorine (Cl) and Bromine (Br) based flame retardants meet JS709B low halogen requirements of <=1000ppm threshold. Antimony trioxide based flame retardants must also meet the <=1000ppm threshold requirement.

(3) MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

(5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

(6) Lead finish/Ball material - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

**Important Information and Disclaimer:**The information provided on this page represents TI's knowledge and belief as of the date that it is provided. TI bases its knowledge and belief on information provided by third parties, and makes no representation or warranty as to the accuracy of such information. Efforts are underway to better integrate information from third parties. TI has taken and continues to take reasonable steps to provide representative and accurate information but may not have conducted destructive testing or chemical analysis on incoming materials and chemicals. TI and TI suppliers consider certain information to be proprietary, and thus CAS numbers and other limited information may not be available for release.

In no event shall TI's liability arising out of such information exceed the total purchase price of the TI part(s) at issue in this document sold by TI to Customer on an annual basis.

**TAPE AND REEL INFORMATION**
