

# CLC520

## Amplifier with Voltage Controlled Gain, AGC +Amp

### General Description

The CLC520 is a wideband DC-coupled amplifier with voltage controlled gain (AGC). The amplifier has a high impedance, differential signal input; a high bandwidth, gain control input; and a single-ended voltage output. Signal channel performance is outstanding with 160MHz small signal bandwidth, 0.5 degree linear phase deviation (to 60MHz) and 0.04% signal nonlinearity at 4V<sub>PP</sub> output.

Gain control is very flexible and easy to use. Maximum gain may be set over a nominal range of 2 to 100 with one external resistor. In addition, the gain control input provides more than 40dB of voltage controlled gain adjustment from the maximum gain setting. For example, a CLC520 may be set for a maximum gain of 2 (or 6dB) for a voltage controlled gain range from 40dB to less than 34dB. Alternatively, the CLC520 could be set for a maximum gain of 100 or (40dB) for a voltage controlled gain range from 40dB to less than 0dB.

The gain control bandwidth of 100MHz is superb for AGC/ALC loop stabilization. And since the gain is minimum with a zero volt input and maximum with a +2 volt input, driving the control input is easy.

Finally, the CLC520 differential inputs, and ground referenced voltage output take the trouble out of designing DC-coupled AGC circuits for display normalizers; signal leveling automatic circuits; etc.

### Enhanced Solutions (Military/Aerospace)

SMD Number: 5962-91694

Space level versions also available.

For more information, visit <http://www.national.com/mil>

### Features

- 160MHz, -3dB bandwidth
- 2000V/μsec slew rate
- 0.04% signal nonlinearity at 4V<sub>PP</sub> output
- -43dB feedthrough at 30MHz
- User adjustable gain range
- Differential voltage input and single-ended voltage output

### Applications

- Wide bandwidth AGC systems
- Automatic signal leveling
- Video signal processing
- Voltage controlled filters
- Differential amplifier
- Amplitude modulation

### Connection Diagram

## Application Information

01275607

**FIGURE 1. CLC520 Simplified Schematic**

### Simplified Circuit Description

A simplified schematic for the CLC520 is given in *Figure 1*.  $+V_{IN}$  and  $-V_{IN}$  are buffered with closed-loop voltage followers inducing a signal current in  $R_g$  proportional to  $(+V_{IN}) - (-V_{IN})$ , the differential input voltage. This current controls a current source which supplies two well matched transistors, Q1 and Q2.

The current flowing through Q2 is converted to the final output voltage using  $R_f$  and output amplifier, U1. By changing the fraction of the signal current  $I$  which flows through Q2 the gain is changed. This is done by changing the voltage applied differentially to the bases of Q1 and Q2. For example, with  $V_g = 0$ , Q1 is on and Q2 is off. With zero signal current of flowing through Q2 into  $R_f$ , the CLC520 is set to minimum gain. Conversely, with  $V_g = 2V$ , Q1 is off and all of the signal current  $I$  flows through Q2 to  $R_f$  producing maximum gain. With  $V_g$  set to 1.1V, the bases of Q1 and Q2 are set to approximately the same voltage, causing their collector currents to equally divide the signal current  $I$ , and establish the gain at one half the maximum gain.

### Typical application circuit

*Figure 2* illustrates a voltage-controlled gain block offering broadband performance in a 50 $\Omega$  system environment. The input signal is applied to pin 3 of the CLC520 and terminating resistor R2. Gain control signals are applied to pin 2. The net gain control port input impedance is 50 $\Omega$ , set by the parallel combination of R1 and the 750 $\Omega$  input impedance of pin 2 of the CLC520.  $R_f$  is set to the standard value, 1k $\Omega$ , and  $R_g$  sets the maximum voltage gain to 10V/V. Output impedance is set by  $R_o$  to 50 $\Omega$  so with 50 $\Omega$  source and load terminations, the gain is approximately 14dB.

01275608

**FIGURE 2. CLC520 Typical Application Circuit**

Capacitors C1-C6 provide broadband power supply bypassing. C2 and C5 should be tantalum capacitors. All other capacitors should be high quality ceramic capacitors (CK-05 or equivalent).

### Adjusting offset

Offset can be broken into two parts; an input-referred term and an output-referred term. The input-referred offset shows up as a variation in output voltage as  $V_g$  is changed. This can be trimmed using the circuit in *Figure 3* by placing a low frequency square wave ( $V_{IN} = 0$  to 2V, into  $V_g$  with  $V_{IN} = 0V$ , the input referred  $V_{os}$  term shows up as a small square wave riding a DC value. Adjust  $R_1$  to null the  $V_{os}$  square wave term to zero. After adjusting the input-referred offset, adjust R2 (with  $V_{IN} = 0$ ,  $V_g = 0$ ) until  $V_{OUT}$  is zero. Finally, for inverting applications  $V_{IN}$  may be applied to pin 6 and the offset adjustment to pin 3. This offset trim does not improve output offset temperature coefficient.

01275628

**FIGURE 3. CLC520 Offset Adjustment Circuitry (other external elements not shown)**

### Selecting component values

Most applications of the CLC520 adjust the gain to maximize the  $V_{OUT}$  signal. When referred back to the input, this means

## Application Information (Continued)

the input signal, signal-to-noise ratio is maximized. The maximum allowed input amplitude and from system specifications, using maximum required gain  $R_f$  and  $R_g$  can be calculated.

The output stage op amp is a current-feedback type amplifier optimized for  $R_f = 1k\Omega$ .  $R_g$  can then be computed as:

$$R_g = \frac{R_f \times 1.85}{A_{Vmax}} - 3.0\Omega \text{ with } R_f = 1k\Omega$$

To determine whether the maximum input amplitude will overdrive the CLC520, compute:

$$V_{dmax} = (R_g + 3.0\Omega) \cdot 0.00135$$

the maximum differential input voltage for linear operation. If the maximum input amplitude exceeds the above  $V_{dmax}$  limit, then CLC520 should either be moved to a location in the signal chain where input amplitudes are reduced, or the CLC520 gain  $A_{VMAX}$  should be reduced or the values for  $R_g$  and  $R_f$  should be increased. The overall system performance impact is different based on the choice made.

If the input amplitude is reduced, recompute the impact on signal-to-noise ratio. If  $A_{VMAX}$  is reduced,

FIGURE 4. CLC520 Noise Model

Post CLC520 amplifier gain, should be increased, or another gain stage added to make up for reduced system gain..

To increase  $R_g$  and  $R_f$ , where  $V_{dmax} = (+V_{IN}) - (-V_{IN})$  the largest expected peak differential input voltage. Compute the lowest acceptable value for  $R_g$ :

$$R_g > 740 \cdot V_{dmax} - 3\Omega$$

Operating with  $R_g$  larger than this value insures linear operation of the input buffers.

$R_f$  may be computed from selected  $R_g$  and  $A_{VMAX}$ :

$$R_f = \frac{A_{Vmax} \times (R_g + 3.0\Omega)}{1.85}$$

$R_f$  should be  $\geq 1k\Omega$  for overall best performance, however  $R_f < 1k\Omega$  can be implemented if necessary using a loop gain reducing resistor to ground on the inverting summing node of the output amplifier (see application note QA-13 for details).

### Printed Circuit Layout

A good high frequency PCB layout including ground plane construction and power supply bypassing close to the package are critical to achieving full performance. The amplifier is sensitive to stray capacitance to ground at the Inverting-input (pin12); keep node trace area small. Shunt

capacitance across the feedback resistor should not be used to compensate for this effect.

For best performance at low maximum gains ( $A_{VMAX} < 10$ )  $R_g$  and  $R_f$  connections should be treated in a similar fashion. Capacitance to ground should be minimized by removing the ground plane from under the resistor of  $R_g$ .

Parasitic or load capacitance directly on the output (pin 10) degrades phase margin leading to frequency response peaking. A small series resistor before this capacitance, effectively reduces this effect (see Settling Time vs. Capacitive Load).

Precision buffered resistors (PRP8351 series from Precision Resistive Products) must be used for  $R_f$  for rated performance. Precision buffered resistors are suggested for  $R_g$  for low gain settings ( $A_{VMAX} < 10$ ). Carbon composition resistors and RN55D metal-film resistors may be used with reduced performance.

Evaluation PC boards (part no. 730021) for the CLC520 are available.

### Predicting the output noise

Seven noise sources ( $e_n$ ,  $i_n$ ,  $i_i$ ,  $i_o$ ,  $i_{no}$ ,  $e_{no}$ ,  $E_{core}$ ) are used to model the CLC520 noise performance (Figure 4).  $e_n$ ,  $i_n$ , and  $i_i$  model the equivalent input noise terms for the input buffer while  $i_o$ ,  $i_{no}$ , and  $e_{no}$  model the noise terms for the output buffer. To simplify the model  $e_n$  includes the effect of resistor  $R_g$  (see Figure 5 for  $e_n$  vs.  $R_g$ ). To simplify the model further,  $R_{bias}$  is assumed noiseless and its noise contribution is included in  $i_o$ .

An additional term  $E_{core}$  mimics the active device noise contribution from the Gilbert multiplier core. Core noise is theoretically zero when the multiplier is set to maximum gain or zero gain ( $V_g > 1.6V$  or  $V_g < 0.63V$  respectively at room temperature) and reaches a maximum of  $37nV/\sqrt{Hz}$  at  $A_{VMAX}/2$ .

FIGURE 5. Equivalent Input Noise Voltage ( $e_n$ ) vs.  $R_g$

Several points should be made concerning this model. First, external component noise contributions need to be factored in when computing total output referred noise. The only exception is  $R_g$ , where its noise contribution is already factored in. Second, the model ignores flicker noise contributions. Applications where noise below approximately 100kHz must be considered should use this model with caution. Third, this model very accurately predicts output noise voltage for the typical application circuit (see above) but accuracy will degrade the component values deviate further from those in the typical application circuit. In general, however,

## Application Information (Continued)

the model should predict the equivalent output noise above the flicker noise region to within a few dB of actual performance over the normal range of  $A_{VMAX}$  and component values.

FIGURE 6. Typical Circuit

FIGURE 7. Noise Model for Typical Circuit

### Calculating CLC520 output noise in a typical circuit

To calculate the noise in a CLC520 application, the noise terms given for the amplifier as well as the noise terms of the external components must be included. To clarify the techniques used, output noise in a typical circuit will be calculated. (Figure 6)

The noise model is depicted in Figure 7. The diagram assumes spot noise source with  $V_{rms}/\sqrt{Hz}$  and  $Amps_{rms}/\sqrt{Hz}$  units. The Thevenin equivalent of the source and input termination is used; 25Ω in series with a noise voltage source.  $R_g$  is assumed noiseless since its effect is included in  $e_n$ . The internal 5kΩ resistor at the CLC520 core output is also assumed noiseless since its effect is included in  $i_{io}$ . The noise contribution from  $R_f$  is modeled as a noise source.

The easiest way to analyze the output noise of this circuit is to divide the noise power into three pieces; –input buffer noise calculation, output buffer noise and core noise. The input buffer varies with the gain. The output buffer term is constant. The core noise term is zero at both maximum and minimum gain and reaches peak at  $A_{VMAX}/2$ .

Since we assume all noise terms are uncorrelated, the equivalent input noise voltage squared is given by:

$$E_{it}^2 = 4kT25 + (i_n 25)^2 + e_n^2$$

$i_i$  does not contribute to the output buffer noise because the input buffer inverting input is grounded.  $e_n$  is taken from Figure 5.

The equivalent output buffer noise is given by:

$$E_{ot}^2 = (i_{io} \cdot 1k\Omega)^2 + 4kT(1k\Omega) + [e_{no} (1 + \frac{1k\Omega}{5k\Omega})]^2$$

$i_{no}$  does not contribute to the output buffer noise because the output buffer non-inverting input is grounded.

The core noise is already output referred and is  $37nV/\sqrt{Hz}$  at  $V_g = 1.1 (A_{VMAX}/2)$  and approaches zero as  $A$  goes to 0 or  $A_{VMAX}$ . Summing the noise power for each term gives the total output noise power.

The total output noise voltage is given by:

$$E_{TOTAL}^2 = E_{it}^2 A_v^2 + E_{ot}^2 + C E_{core}^2$$

Where  $A_v$  is the input to output voltage gain, which varies with  $V_g$ .

$C$  accounts for the variation in core noise contribution as  $V_g$  is adjusted.  $C=1$  when gain  $A_v$  is  $A_{VMAX}/2$ .  $C$  is zero at  $A_{VMAX}$  and  $A_v = 0$  and varies between 0 and 1 for all other values.

Using these equations, total calculated output noise for the circuit was  $20nV/\sqrt{Hz}$  at minimum gain,  $49nV/\sqrt{Hz}$  at mid-gain, and  $53nV/\sqrt{Hz}$  at maximum gain.

FIGURE 8. Automatic Gain Control (AGC) Loop

### AGC circuits

Figure 8 shows a typical AGC circuit. The CLC520 is followed up with a CLC401 for higher overall gain. The output of the CLC401 is rectified and fed to an inverting integrator using a CLC420 (wideband voltage feedback op amp). When the output voltage,  $V_{OUT}$ , is too large the integrator output voltage ramps down reducing the net gain of the CLC520 and  $V_{OUT}$ . If the output voltage is too small, the integrator ramps up increasing the net gain and the output voltage. Actual output level is set with  $R_1$ . To prevent shifts in DC output voltage with DC changes in input signal level, trim pot  $R_2$  is provided. AGC circuits are always limited in the range of input signals over which constant output level can be maintained. In this circuit, we would expect that reasonable AGC action could be maintained over the gain adjustment range of the CLC520 (at least 40dB). In practice, rectifier dynamic range limits reduce this slightly.

### Evaluation Board

Evaluation PC boards (part number 730029 for through-hole and 730023 for SOIC) for the CLC520 are available.
