

FEATURES**Dual Matched PNP Transistor****Low Offset Voltage: 100 μ V max****Low Noise: 1 nV/ $\sqrt{\text{Hz}}$ @ 1 kHz max****High Gain: 100 min****High Gain Bandwidth: 190 MHz typ****Tight Gain Matching: 3% max****Excellent Logarithmic Conformance: $r_{\text{BE}} \approx 0.3 \Omega$ typ****Available in Die Form****PIN CONNECTION****TO-78
(H Suffix)****GENERAL DESCRIPTION**

The MAT03 dual monolithic PNP transistor offers excellent parametric matching and high frequency performance. Low noise characteristics (1 nV/ $\sqrt{\text{Hz}}$ max @ 1 kHz), high bandwidth (190 MHz typical), and low offset voltage (100 μ V max), makes the MAT03 an excellent choice for demanding preamplifier applications. Tight current gain matching (3% max mismatch) and high current gain (100 min), over a wide range of collector current, makes the MAT03 an excellent choice for current mirrors. A low value of bulk resistance (typically 0.3 Ω) also makes the MAT03 an ideal component for applications requiring accurate logarithmic conformance.

Each transistor is individually tested to data sheet specifications. Device performance is guaranteed at 25°C and over the extended industrial and military temperature ranges. To insure the long-term stability of the matching parameters, internal protection diodes across the base-emitter junction clamp any reverse base-emitter junction potential. This prevents a base-emitter breakdown condition which can result in degradation of gain and matching performance due to excessive breakdown current.

NOTES

¹Current gain is measured at collector-base voltages (V_{CB}) swept from 0 to V_{MAX} at indicated collector current. Typical values are measured at V_{CB} = 0 V.

²Current gain matching (Δh_{FE}) is defined as: $\Delta h_{FE} = \frac{100 (\Delta_B) h_{FE} (\min)}{I_C}$

³Offset voltage is defined as: V_{OS} = V_{BE1} - V_{BE2}, where V_{OS} is the differential voltage for I_{C1} = I_{C2}: $V_{OS} = V_{BE1} - V_{BE2} = \frac{KT}{q} \ln \left(\frac{I_{C1}}{I_{C2}} \right)$.

⁴Sample tested. Noise tested and specified as equivalent input voltage for each transistor.

⁵Guaranteed by V_{OS} test (TCV_{OS} = V_{OS}/T for V_{OS} ≪ V_{BE}) where T = 298 K for T_A = 25°C.

Specifications subject to change without notice.

WAFER TEST LIMITS (at 25°C, unless otherwise noted.)

Parameter	Symbol	Conditions	MAT03N Limits	Units
Breakdown Voltage	BV_{CEO}		36	V min

ABSOLUTE MAXIMUM RATINGS¹

Collector-Base Voltage (BV_{CBO})	36 V
Collector-Emitter Voltage (BV_{CEO})	36 V
Collector-Collector Voltage (BV_{CC})	36 V
Emitter-Emitter Voltage (BV_{EE})	36 V
Collector Current (I_C)	20 mA
Emitter Current (I_E)	20 mA
Total Power Dissipation	
Ambient Temperature $\leq 70^\circ C$ ²	500 mW
Operating Temperature Range	
MAT03A	-55°C to +125°C
MAT03E/F	-40°C to +85°C
Operating Junction Temperature	-55°C to +150°C
Storage Temperature	-65°C to +150°C
Lead Temperature (Soldering, 60 sec)	+300°C
Junction Temperature	-65°C to +150°C

ORDERING GUIDE¹

Model	V_{OS} max (T _A = +25°C)	Temperature Range	Package Option
MAT03AH ²	100 μV	-55°C to +125°C	TO-78
MAT03EH	100 μV	-40°C to +85°C	TO-78
MAT03FH	200 μV	-40°C to +85°C	TO-78

NOTES

¹Absolute maximum ratings apply to both DICE and packaged devices.
²Rating applies to TO-78 not using a heat sink, and LCC; devices in free air only. For TO-78, derate linearly at 6.3 mW/°C above 70°C ambient temperature; for LCC, derate at 7.8 mW/°C.

NOTES

¹Burn-in is available on industrial temperature range parts.
²For devices processed in total compliance to MIL-STD-883, add/883 after part number. Consult factory for 883 data sheet.

CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although the MAT03 features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

APPLICATIONS INFORMATION

MAT03 MODELS

The MAT03 model (Figure 12) includes parasitic diodes D₃ through D₆. D₁ and D₂ are internal protection diodes which prevent zenering of the base-emitter junctions.

The analysis programs, SPICE and SABER, are primarily used in evaluating the functional performance of systems. The models are provided only as an aid in utilizing these simulation programs.

MAT03 NOISE MEASUREMENT

All resistive components (Johnson noise, $e_n^2 = 4kTB R$, or $e_n = 0.13\sqrt{R}$ nV/ \sqrt{Hz} , where R is in k Ω) and semiconductor junctions (Shot noise, caused by current flowing through a junction, produces voltage noise in series impedances such as transistor-collector load resistors, $I_n = 0.566\sqrt{I}$ pA/ \sqrt{Hz} where I is in μ A) contribute to the system input noise.

Figure 13 illustrates a technique for measuring the equivalent input noise voltage of the MAT03. 1 mA of stage current is used

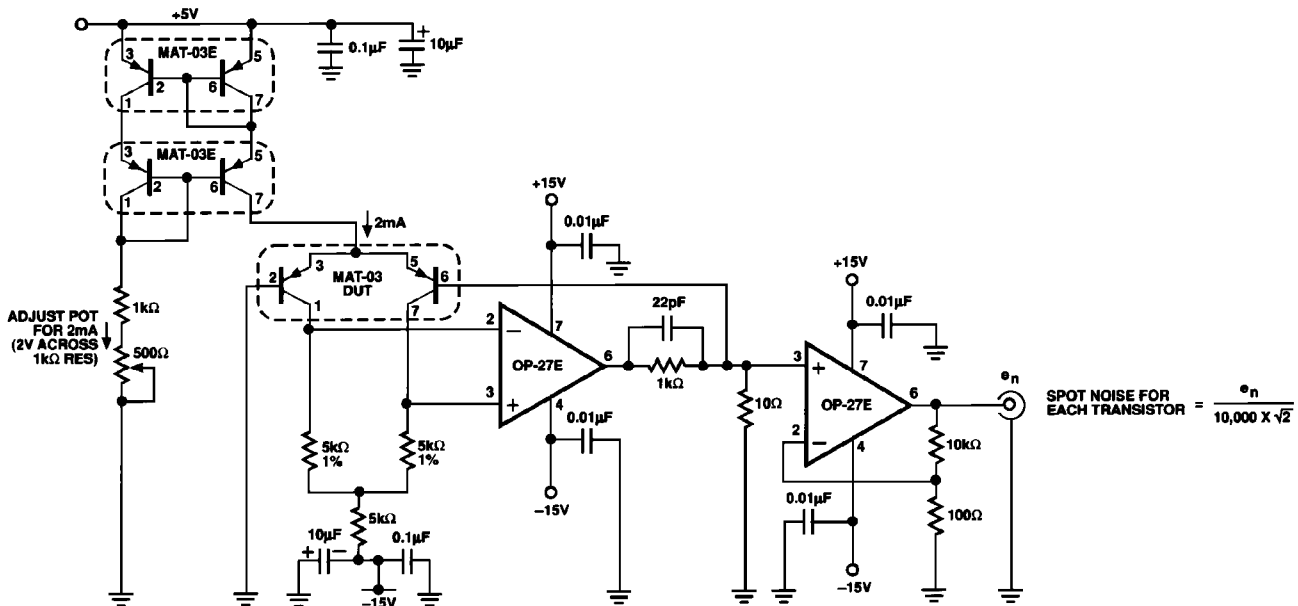

Figure 13. MAT03 Voltage Noise Measurement Circuit

to bias each side of the differential pair. The 5 kΩ collector resistors noise contribution is insignificant compared to the voltage noise of the MAT03. Since noise in the signal path is referred back to the input, this voltage noise is attenuated by the gain of the circuit. Consequently, the noise contribution of the collector load resistors is only 0.048 nV/√Hz. This is considerably less than the typical 0.8 nV/√Hz input noise voltage of the MAT03 transistor.

The noise contribution of the OP27 gain stages is also negligible due to the gain in the signal path. The op amp stages amplify the input referred noise of the transistors to increase the signal strength to allow the noise spectral density ($e_{in} \times 10000$) to be measured with a spectrum analyzer. And, since we assume equal noise contributions from each transistor in the MAT03, the output is divided by $\sqrt{2}$ to determine a single transistor's input noise.

Air currents cause small temperature changes that can appear as low frequency noise. To eliminate this noise source, the

measurement circuit must be thermally isolated. Effects of extraneous noise sources must also be eliminated by totally shielding the circuit.

SUPER LOW NOISE AMPLIFIER

The circuit in Figure 14a is a super low noise amplifier with equivalent input voltage noise of 0.32 nV/√Hz. By paralleling three MAT03 matched pairs, a further reduction of amplifier noise is attained by a reduction of the base spreading resistance by a factor of 3, and consequently the noise by $\sqrt{3}$. Additionally, the shot noise contribution is reduced by maintaining a high collector current (2 mA/device) which reduces the dynamic emitter resistance and decreases voltage noise. The voltage noise is inversely proportional to the square root of the stage current, and current noise increases proportionally to the square root of the stage current. Accordingly, this amplifier capitalizes on voltage noise reduction techniques at the expense of increasing the current noise. However, high current noise is not usually important when dealing with low impedance sources.

$A_V = 10$
 $C_T = 30pF$

Figure 14a. Super Low Noise Amplifier

MAT03

This amplifier exhibits excellent full power ac performance, 0.08% THD into a 600 Ω load, making it suitable for exacting audio applications (see Figure 14b).

Figure 14b. Super Low Noise Amplifier—Total Harmonic Distortion

LOW NOISE MICROPHONE PREAMPLIFIER

Figure 15 shows a microphone preamplifier that consists of a MAT03 and a low noise op amp. The input stage operates at a relatively high quiescent current of 2 mA per side, which reduces the MAT03 transistor's voltage noise. The $1/f$ corner is less than 1 Hz. Total harmonic distortion is under 0.005% for a 10 V p-p signal from 20 Hz to 20 kHz. The preamp gain is 100, but can be modified by varying R_5 or R_6 ($V_{OUT}/V_{IN} = R_5/R_6 + 1$).

A total input stage emitter current of 4 mA is provided by Q_2 . The constant current in Q_2 is set by using the forward voltage of a GaAsP LED as a reference. The difference between this voltage

and the V_{BE} of a silicon transistor is predictable and constant (to a few percent) over a wide temperature range. The voltage difference, approximately 1 V, is dropped across the 250 Ω resistor which produces a temperature stabilized emitter current.

CURRENT SOURCES

A fundamental requirement for accurate current mirrors and active load stages is matched transistor components. Due to the excellent V_{BE} matching (the voltage difference between V_{BE} 's required to equalize collector current) and gain matching, the MAT03 can be used to implement a variety of standard current mirrors that can source current into a load such as an amplifier stage. The advantages of current loads in amplifiers versus resistors is an increase of voltage gain due to higher impedances, larger signal range, and in many applications a wider signal bandwidth.

Figure 16 illustrates a cascode current mirror consisting of two MAT03 transistor pairs.

The cascode current source has a common base transistor in series with the output which causes an increase in output impedance of the current source since V_{CE} stays relatively constant. High frequency characteristics are improved due to a reduction of Miller capacitance. The small-signal output impedance can be determined by consulting "h_{OF} vs. Collector Current" typical graph. Typical output impedance levels approach the performance of a perfect current source.

Considering a typical collector current of 100 μA, we have:

$$r_{oQ3} = \frac{1}{1.0 \mu\text{MHOS}} = 1 \text{ M}\Omega$$

Figure 15. Low Noise Microphone Preamplifier

Q₂ and Q₃ are in series and operate at the same current levels so the total output impedance is:

$$R_O = h_{FE} r_{OQ3} @ (160)(1 M\Omega) = 160 M\Omega.$$

Figure 16. Cascode Current Source

CURRENT MATCHING

The objective of current source or mirror design is generation of currents that are either matched or must maintain a constant ratio. However, mismatch of base-emitter voltages cause output current errors. Consider the example of Figure 17a. If the resistors and transistors are equal and the collector voltages are the same, the collector currents will match precisely. Investigating the current-matching errors resulting from a nonzero V_{OS}, we define ΔI_C as the current error between the two transistors.

Graph 17b describes the relationship of current matching errors versus offset voltage for a specified average current I_C. Note that since the relative error between the currents is exponentially proportional to the offset voltage, tight matching is required to design high accuracy current sources. For example, if the offset voltage is 5 mV at 100 μA collector current, the current matching error would be 20%. Additionally, temperature effects such as offset drift (3 μV/°C per mV of V_{OS}) will degrade performance if Q₁ and Q₂ are not well matched.

Since Q₂ buffers Q₃, both transistors in the MAT03, Q₁ and Q₃, maintain the same collector current. D₂ and D₃ form a Baker clamp which prevents Q₂ from turning off, thereby improving the switching speed of the current mirror. The feedback serves to increase the output impedance and improves accuracy by reducing the base-width modulation which occurs with varying collector-emitter voltages. Accuracy and linearity performance of the current pump is summarized in Figure 19.

Figure 17a. Current Matching Circuit

Figure 17b. Current Matching Accuracy % vs. Offset Voltage

DIGITALLY PROGRAMMABLE BIPOLAR CURRENT PUMP

The circuit of Figure 18 is a digitally programmable current pump. The current pump incorporates a DAC08, and a fast Wilson current source using the MAT03. Examining Figure 18, the DAC08 is set for 2 mA full-scale range so that bipolar current operation of ±2 mA is achieved. The Wilson current mirror maintains linearity within the LSB range of the 8-bit DAC08 (±2 mA/256 = 15.6 μA resolution) as seen in Figure 19. A negative feedback path established by Q₂ regulates the collector current so that it matches the reference current programmed by the DAC08.

Collector-emitter voltages across both Q₁ and Q₃ are matched by D₁, with Q₃'s collector-emitter voltage remaining constant, independent of the voltage across the current source output.

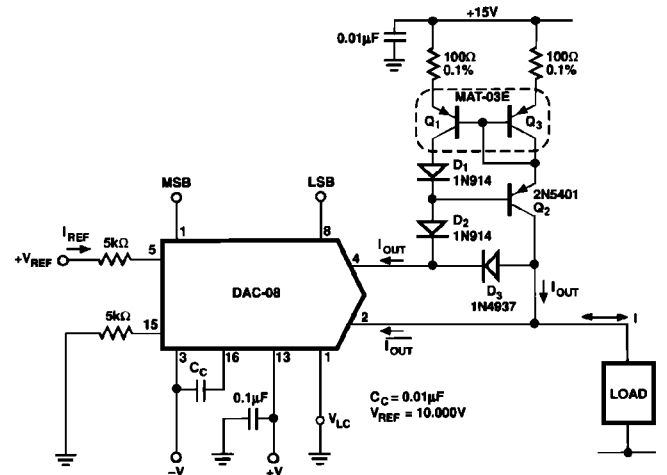

Figure 18. Digitally Programmable Bipolar Current Pump

Figure 19. Digitally Programmable Current Pump—INL Error as Digital Code

The full-scale output of the DAC08, I_{OUT} , is a linear function of I_{REF}

$$I_{FR} = \frac{256}{256} \times I_{REF}, \text{ and } I_{OUT} + \overline{I_{OUT}} = I_{REF} \frac{256}{256}$$

The current mirror output is $I_{OUT} - \overline{I_{OUT}} = 1$, so that if

$$I_{REF} = 2 \text{ mA}:$$

$$I = 2 I_{OUT} - 1.992 \text{ mA}$$

$$= 2 \left(\frac{\text{Input Code}}{256} \right) (2 \text{ mA}) - 1.992 \text{ mA}.$$
