

# GaNFast™ Power IC with GaNSense™ Technology

#### GaNFast™ Power IC

- · Monolithically-integrated gate drive
- Wide V<sub>CC</sub> range (10 to 30 V)
- Programmable turn-on dV/dt
- 200 V/ns dV/dt immunity
- · 800 V Transient Voltage Rating
- · 700 V Continuous Voltage Rating
- Low 170 mΩ resistance
- · Zero reverse recovery charge
- · 2 MHz operation

#### GaNSense™ Technology

- · Integrated loss-less current sensing
- · Short-circuit protection
- Over-temperature protection
- · Autonomous low-current standby mode
- · Auto-standby mode input

#### Small, low-profile SMT QFN

- 6 x 8 mm footprint, 0.85 mm profile
- · Minimized package inductance
- · Large cooling pad

#### Sustainability

- · RoHS, Pb-free, REACH-compliant
- Up to 40% energy savings vs Si solutions
- System level 4kg CO<sub>2</sub> Carbon Footprint reduction

#### **Product Reliability**

 20-year limited product warranty (see Section 14 for details)

#### 2. Topologies / Applications

- · AC-DC, DC-DC, DC-AC
- · QR flyback, ACF, Buck, Boost, Half bridge, Full bridge, LLC resonant, Class D, PFC
- · Wireless power, Solar Micro-inverters
- · LED lighting, TV SMPS, Server, Telecom

# 4. Typical Application Circuits

Loss-less Current Sensing

QFN 6 x 8 mm

Simplified schematic

#### 3. Description

This GaNFast™ power IC integrates a high performance eMode GaN FET with integrated gate drive to achieve unprecedented high-frequency and high efficiency operation. GaNSense™ technology is also integrated which enables real-time, accurate sensing of voltage, current and temperature to further improve performance and robustness not achieved by any discrete GaN or discrete silicon device. GaNSense™ enables integrated loss-less current sensing which eliminates external current sensing resistors and increases system efficiency. GaNSense™ also enables short circuit and over-temperature protection to increase system robustness, while auto-standby mode increases light, tiny & no-load efficiency. These GaN ICs combine the highest dV/dt immunity, high-speed integrated drive and industrystandard low-profile, low-inductance, SMT QFN packaging to enable designers to achieve simple, quick and reliable solutions. Navitas' GaN IC technology extends the capabilities of traditional topologies such as flyback, half-bridge, buck/boost, LLC and other resonant converters to reach MHz+ frequencies with very high efficiencies and low EMI to achieve unprecedented power densities at a very attractive cost structure.

#### 8. Functional Description

The following functional description contains additional information regarding the IC operating modes and pin functionality.

#### 8.1. GaN Power IC Connections and Component Values

The typical connection diagram for this GaN Power IC is shown in Fig. 20. The IC pins include drain of the GaN power FET (D), source of the GaN power FET (S), IC supply ( $V_{CC}$ ), gate drive supply ( $V_{DD}$ ), gate drive turn-on control SET input ( $R_{DD}$ ), PWM input (PWM), separate signal GND ( $S_{GND}$ ), current sensing output (CS), auto-standby mode input ( $\overline{STBY}$ ), and 5V supply (5V). The Source pad and Source pins (S) should all be connected to the system  $P_{GND}$ .  $S_{GND}$  pin 4 must be connected directly to Source PAD underneath IC. The Source pins (S) should each be connected externally to the Source pad directly underneath the IC. The Drain Pins (D) should all be shorted together by copper in the layout (see Section 9). The external components around the IC include  $V_{CC}$  filter capacitor ( $C_{VCC}$ ) connected between  $V_{CC}$  pin and  $S_{GND}$  pin,  $V_{DD}$  filter capacitor ( $C_{VDD}$ ) connected between  $V_{DD}$  pin and  $S_{GND}$  pin, turn-on dV/dt set resistor ( $R_{DD}$ ) connected in between  $V_{DD}$  pin and  $R_{DD}$  pin, a current sense amplitude set resistor ( $R_{SET}$ ) connected between CS pin and  $S_{GND}$ , and auto-standby mode pin ( $\overline{STBY}$ ) connected to  $S_{GND}$ . An external capacitor ( $C_{CS}$ ), 0.01uF max) is required between pin 5V and  $S_{GND}$ . This 5V pin is for internal purposes only and must not be used for biasing external circuitry.

Fig. 20. IC connection diagram

The following table (Table I) shows the recommended component values (typical only) for the external components connected to the pins of this GaN power IC. These components should be placed as close as possible to the IC. Please see PCB Layout Guidelines for more information.

SYM	DESCRIPTION	ТҮР	UNITS
C <sub>VCC</sub>	V <sub>CC</sub> supply capacitor	0.1	μF
C <sub>VDD</sub>	V <sub>DD</sub> supply capacitor	0.010	μF
R <sub>DD</sub>	Gate drive turn-on current set resistor	50	Ω
R <sub>SET</sub>	Current sense amplitude set resistor	Depends on system design (See Section 8.6 , Equation 1)	Ω
C <sub>5V</sub>	5V supply capacitor	10 (Max)	nF

Table I. Recommended component values (typical only).

Final Datasheet 13 Rev Oct. 11, 2022

#### 8.1. GaN Power IC Connections and Component Values (Cont.)

The typical connection diagram for a half-bridge configuration is shown in Fig. 21. The schematic includes a low-side GaN IC with the Source connected to  $P_{GND}$  and a high-side GaN IC with the Drain connected to  $V_{IN}$ . The Source of the high-side GaN IC is connected to the Drain of the low-side GaN IC to form the half-bridge switched node output ( $V_{SW}$ ). The external components for each GaN IC are placed directly next to their respective pins. A low-side supply voltage (9-24V) is required for  $V_{CC}$  of the low-side GaN IC and a bootstrap diode and resistor ( $D_{BOOT}$ ,  $R_{BOOT}$ ) provide the necessary high-side supply voltage from  $V_{CC}$  to  $V_B$ . The low-side GaN IC includes low-side PWM input (PWML) and a low-side current sense output ( $CS_{OUTL}$ ). The high-side GaN IC requires a high-side 'floating' PWM input signal for driving the PWMH input (typically provided by an external half-bridge driver, not shown). The  $R_{BOOT}$  and  $C_{VB}$  should be carefully selected such that the time constant of the  $R_{BOOT}$  x  $C_{VB}$  is greater than 0.5  $\mu$ s (5  $\Omega$  x 100 nF).

SYM	DESCRIPTION	ТҮР	UNITS
C <sub>VCC</sub>	V <sub>CC</sub> supply capacitor	0.1	μF
C <sub>VB</sub>	V <sub>DB</sub> supply capacitor	100	nF
C <sub>VDDL, H</sub>	V <sub>DD</sub> supply capacitor	10	nF
R <sub>DDL, H</sub>	Gate drive turn-on current set resistor	50	Ω
R <sub>SETL, H</sub>	Current sense amplitude set resistor	Depends on system design (See Section 8.6. Equation 1)	Ω
C <sub>5VL, H</sub>	5V supply capacitor	10 (Max)	nF
R <sub>BOOT</sub>	Bootstrap resistor	5	Ω

Table II. Recommended component values (typical only)

Final Datasheet 14 Rev Oct. 11, 2022

#### 8.2. UVLO Mode

This GaN Power IC includes under-voltage lockout (UVLO) circuits for properly disabling all of the internal circuitry when  $V_{CC}$  is below the  $V_{CCUV^+}$  threshold (8.5V, typical) and  $V_{DD}$  is below the  $V_{DDUV^+}$  threshold (4.5V, typical). During UVLO Mode, the internal gate drive and power FET are disabled and  $V_{CC}$  consumes a low quiescent current (275 $\mu$ A, typical). As the  $V_{CC}$  supply voltage increases (Fig. 22), the voltage at the  $V_{DD}$  pin also increases and exceeds  $V_{DDUV^+}$ . The  $V_{DD}$  voltage continues to increase with  $V_{CC}$  until it gets limited to a constant voltage level (6.2V, typical) by the internal regulator. The  $V_{CC}$  voltage continues to increase until it exceeds  $V_{CCUV^+}$  and the IC enters Normal Operating Mode. The gate drive is enabled and the control signal at the PWM input turns the internal GaN power FET on and off normally. During system power off, when  $V_{CC}$  decreases below the  $V_{CCUV^-}$  threshold (7.3V, typical), the gate drive is disabled and the IC enters UVLO Mode.

Fig. 22. UVLO Mode timing diagram

Final Datasheet 15 Rev Oct. 11, 2022

#### 8.3. Normal Operating Mode

During Normal Operating Mode, all of the internal circuit blocks are active.  $V_{CC}$  is above 9V,  $V_{DD}$  is maintained at 6.2V by the internal voltage regulator, and the internal gate drive and power FET are both enabled. The external PWM signal at the PWM pin determines the frequency and duty-cycle of the internal gate of the power FET. As the PWM voltage toggles above and below the rising and falling input thresholds (2.8V and 1.1V), the internal power FET toggles on and off (Fig. 23). The drain of the power FET then toggles between the source voltage (power ground) and a higher voltage level (700V, max), depending on the external power conversion circuit topology. During each on-time, the CS pin outputs a voltage signal from the internal loss-less current sensing circuit. This circuit measures the current flowing in the GaN power FET without the need for an external current sensing resistor (see section 8.6 GaNSense Technology Loss-Less Current Sensing).

Fig.23. Normal operating mode timing diagram

Final Datasheet 16 Rev Oct. 11, 2022

#### 8.4. Low Power Standby Mode

This GaN Power IC includes an autonomous Low Power Standby Mode for disabling the IC and reducing the  $V_{CC}$  current consumption. During Normal Operating Mode, the PWM pin toggles high and low to turn the GaN power FET on and off. If the input pulses at the PWM pin stop and stay below the lower  $V_{PWML}$  turn-off threshold (1.1V, typical) for the duration of the internal timeout standby delay ( $t_{TO\_STBY}$ , 90usec, typical), then the IC will automatically enter Low Power Standby Mode (Fig. 24). This will disable the gate drive and other internal circuitry and reduce the  $V_{CC}$  supply current to a low level (275uA, typical). When the PWM pulses restart, the IC will wake up instantly at the first rising edge of the PWM input and enter Normal Operating Mode again. To enable auto Standby Mode, the auto-standby mode pin ( $\overline{STBY}$ ) should always be connected to  $S_{GND}$  (set low). To disable auto Standby Mode,  $\overline{STBY}$  pin should be connected to the 5V pin (set high).

Fig.24. Autonomous Low Power Standby Mode timing diagram

#### 8.5. Programmable Turn-on dV/dt Control

During first start-up pulses or during hard-switching conditions, it is desirable to limit the slew rate (dV/dt) of the drain of the power FET during turn-on. This is necessary to reduce EMI or reduce circuit switching noise. To program the turn-on dV/dt rate of the internal power FET, a resistor ( $R_{DD}$ ) is placed in between the  $V_{DD}$  pin 30 and the  $R_{DD}$  pin 29. This resistor ( $R_{DD}$ ) sets the turn-on current of the internal gate driver and therefore sets the turn-on falling edge dV/dt rate of the drain of the power FET (Fig. 25).

Fig. 25. Turn-on dV/dt slew rate control

Final Datasheet 17 Rev Oct. 11, 2022

## 8.6. GaNSense<sup>™</sup> Technology Loss-Less Current Sensing

For many applications it is necessary to sense the cycle-by-cycle current flowing through the power FET. Existing current sensing solutions include placing a current sensing resistor in between the source of the power FET and P<sub>GND</sub>. This resistor method increases system conduction power losses, creates a hotspot on the PCB, and lowers overall system efficiency. To eliminate this external resistor and hotspot, and increase system efficiency, this IC includes GaNSense<sup>TM</sup> Technology for integrated and accurate loss-less current sensing. The current flowing through the internal GaN power FET is sensed internally and then converted to a current at the current sensing output pin (CS). An external resistor (R<sub>SET</sub>) is connected from the CS pin to the S<sub>GND</sub> pin and is used to set the amplitude of the CS pin voltage signal (Fig. 26). This allows for the CS pin signal to programmed to work with different controllers with different current sensing input thresholds.

Fig. 26. Current sensing circuit and timing diagram

When comparing GaNSense<sup>TM</sup> Technology versus existing external resistor sensing method (Fig. 27), the total ON resistance, R<sub>ON(TOT)</sub>, can be substantially reduced. For a 65W high-frequency QR flyback circuit, for example, R<sub>ON(TOT)</sub> is reduced from 340m to 170m. The power loss savings by eliminating the external resistor results in a +0.5% efficiency benefit for the overall system.

Fig. 27. External resistor sensing vs. GaNSense™ Technology

Final Datasheet 18 Rev Oct. 11, 2022

# 8.6 GaNSense<sup>™</sup> Technology Loss-Less Current Sensing (cont.)

To select the correct  $R_{\text{SET}}$  resistor value, the following equation (Equation 1) can be used. This equation uses the equivalent desired external current sensing resistor value ( $R_{\text{CS}}$ ), together with the gain of the internal sensing circuitry, to generate the equivalent  $R_{\text{SET}}$  resistor value. This  $R_{\text{SET}}$  value will give then give the correct voltage level at the CS pin to be compatible with the internal current sensing threshold of the system controller.

$$I_{OUT} \ Ratio = \frac{I_{DS}}{I_{CS}} = \frac{4.4A}{0.00125A} = 3520$$
 $R_{SET} = 3520 * R_{CS}$ 
 $3520 * 170m\Omega = 598.4\Omega$ 

Equation 1. R<sub>SET</sub> resistor value equation

#### 8.7. Over Current Protection (OCP)

This GaN Power IC includes cycle-by-cycle over-current detection and protection (OCP) circuitry to protect the GaN power FET against high current levels. During the on-time of each switching cycle, should the peak current exceed the internal OCP threshold (1.9V, typical), then the internal gate drive will turn the GaN power FET off quickly and truncate the on-time period to prevent damage from occurring to the IC. The IC will then turn on again at the next PWM rising edge at the start of the next on-time period (Fig. 28). This OCP protection feature will self-protect the IC each switching cycle against fast peak over current events and greatly increase the robustness and reliability of the system. The actual peak current threshold can be calculated using Equation 2 and is a function of the internal current-sensing ratio and the external R<sub>SET</sub> resistor. The internal OCP threshold (1.9V, typical) is much higher than the OCP thresholds of many popular QR, ACF and PFC controllers. This ensures good compatibility of this IC with existing controllers without OCP threshold conflicts.

Fig. 28. OCP threshold timing diagram

$$I_{OCP} = \frac{[\ 1.9\ V\ x\ 3520\ ]}{R_{SET}}$$

Equation 2. OCP current threshold equation

Final Datasheet 19 Rev Oct. 11, 2022

#### 8.8. Over Temperature Protection (OTP)

This GaN Power IC includes over-temperature detection and protection (OTP) circuitry to protect the IC against excessively high junction temperatures ( $T_J$ ). High junction temperatures can occur due to overload, high ambient temperatures, and/or poor thermal management. Should  $T_J$  exceed the internal  $T_{OTP^+}$  threshold (165C, typical) then the IC will latch off safely. When  $T_J$  decreases again and falls below the internal  $T_{OTP^+}$  threshold (105C, typical), then the OTP latch will be reset. Until then, internal OTP latch guaranteed to remain in the correct state while  $V_{CC}$  is greater than 5V. During an OTP event, this GaN IC will latch off and the system  $V_{CC}$  supply voltage will decrease due to the loss of the aux winding supply. The system  $V_{CC}$  will fall below the lower UV- threshold of the controller and the high-voltage start-up circuit will turn-on and  $V_{CC}$  will increase again (Fig. 29).  $V_{CC}$  will increase above the rising UV+ threshold and the controller turn on again and deliver PWM pulses again.

Fig. 29. OTP threshold timing diagram

Final Datasheet 20 Rev Oct. 11, 2022

#### 8.9. Drain-to-Source Voltage Considerations

GaN Power ICs have been designed and tested to provide significant design margin to handle transient and continuous voltage conditions that are commonly seen in single-ended topologies, such as quasi-resonant (QR) flyback applications. The different voltage levels and recommended margins in a typical QR flyback can be analyzed using Fig. 30. When the device is switched off, the energy stored in the transformer leakage inductance will cause VDS to overshoot to the level of VSPIKE. The clamp circuit should be designed to control the magnitude of VSPIKE. It is recommended to apply an 80% derating from VDS (TRAN) rating (800V) to 700 V max for repetitive VDS spikes under the worst case steady-state operating conditions. After dissipation of the leakage energy, the device VDS will settle to the level of the bus voltage plus the reflected output voltage which is defined in Fig. 30 as VPLATEAU. It is recommended to design the system such that VPLATEAU follows a typical derating of 80% (560V) from VDS (CONT) (700V). Finally, VDS (TRAN) (800V) rating is also provided for events that occur on a non-repetitive basis, such as line surge, lightning strikes, start-up, over-current, short-circuit, load transient, and output voltage transition. 800V VDS(TRAN) ensures excellent device robustness and no-derating is needed for these non-repetitive events, assuming the surge duration is < 100 µs. For half-bridge based topologies, such as LLC, VDS voltage is clamped to the bus voltage. VDS should be designed such that it meets the VPLATEAU derating guideline (560V).

#### 9. PCB Layout Guidelines

For best electrical and thermal results, these PCB layout guidelines (and 4 steps below) must be followed:

- 1) Place IC components as close as possible to the GaN IC. Place R<sub>SET</sub> resistor directly next to CS pin to minimize high frequency switching noise.
- 2) Connect the ground of IC components to  $S_{GND}$  pin 4 to minimize high frequency switching noise. Connect  $S_{GND}$  pin 4 directly to Source PAD underneath IC.
- 3) Route all connections on single layer. This allows for large thermal copper areas on other layers.
- 4) Place large copper areas on and around Source pad.
- 5) Place many thermal vias inside Source pad and inside source copper areas.
- 6) Place large as possible copper areas on all other layers (bottom, top, mid1, mid2).

**Step 1**. Place GaN IC and components on PCB. Place components as close as possible to IC!

Large

**Step 2**. Route all connections on single layer. Make large copper areas on and around Source pad!

**Step 3**. Place many thermal vias inside source pad and inside source copper areas. (dia=0.65mm, hole=0.33mm, pitch=0.925mm, via wall=1mil)

**Step 4**. Place large copper areas on other layers. Make all thermal copper areas as large as possible!

#### 14. 20-Year Limited Product Warranty

The 20-year limited warranty applies to all packaged Navitas GaNFast Power ICs in mass production, subject to the terms and conditions of, Navitas' express limited product warranty, available at <a href="https://navitassemi.com/terms-conditions">https://navitassemi.com/terms-conditions</a>. The warranted specifications include only the MIN and MAX values only listed in Absolute Maximum Ratings, ESD Ratings and Electrical Characteristics sections of this datasheet. Typical (TYP) values or other specifications are not warranted.

#### 15. Revision History

Date	Status	Notes
Dec. 17, 2021	FINAL	First publication
Apr. 13, 2022	FINAL	Increased $V_{\text{DD6}}$ Max to 6.6V; increased $V_{\text{CCUV+}}$ Max to 9.3V; added 20-Year Limited Product Warrenty
Oct. 10, 2022	FINAL	Added Carbon Neutral certificate
