## FEATURES

- 4.5 V to 18 V Operating Input Voltage
- Up to $99 \%$ Duty Cycle Operation
- Up to 2A Programmable Charging Current
- $\pm 0.75 \%$ Full Battery Voltage Accuracy
- 4.03 V and 3.99 V Selection for Full Battery Voltage
- Full Integrated Power Switches
- Internal Loop Compensation
- No External Reverse Blocking Diode Required
- Preconditioning for Fully Depleted Battery
- Charging Operation Indicator
- Programmable Safety Timer
- Thermal Shutdown Protection
- Cycle-by-Cycle Over Current Protection
- Battery Temperature Monitor and Protection

## APPLICATIONS

- Smart Phones
- Portable Hand-held Solutions
- Portable Media Players

All MPS parts are lead-free and adhere to the RoHS directive. For MPS green status, please visit MPS website under Products, Quality Assurance page.

## TYPICAL APPLICATION

ORDERING INFORMATION

| Part Number* | Package | Top Marking |
| :---: | :---: | :---: |
| MP2615BGQ | QFN-16 $(3 \mathrm{~mm} \times 3 \mathrm{~mm})$ | AJC |

* For Tape \& Reel, add suffix -Z (e.g. MP2615BGQ-Z);

PACKAGE REFERENCE

ABSOLUTE MAXIMUM RATINGS ..... (1)
$V_{s w}$ ..... -0.3 V to 23 V
$\mathrm{V}_{\text {IN }}, \mathrm{V}_{\text {ACOK }}, \mathrm{V}_{\text {CHGOK }}$ ..... -0.3 V to 23 V
$V_{\text {BAtT }} V_{\text {CSP }}$ ..... -0.3 V to 12 V
$V_{\text {BST }}$ ..... $\mathrm{V}_{\mathrm{sw}}+6 \mathrm{~V}$
All Other Pins ..... -0.3 V to 6 V
Junction Temperature ..... $150^{\circ} \mathrm{C}$
Lead Temperature ..... $260^{\circ} \mathrm{C}$
Continuous Power Dissipation ( $\mathrm{T}_{\mathrm{A}}=+25^{\circ} \mathrm{C}$ ) ..... (2) ..... 2.5W
Operating Temperature ..... $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$
Recommended Operating Conditions ..... (3)
$V_{\text {IN }}$ ..... 4.5 V to 18 V
$V_{\text {batt }}$ 2 V to 4.03 V

## Thermal Resistance ${ }^{(4)} \quad \theta_{J A} \quad \theta_{J C}$ QFN-16 (3mmx3mm).............. $50 \ldots . . .12 \ldots{ }^{\circ} \mathrm{C} / \mathrm{W}$

## Notes:

1) Exceeding these ratings may damage the device.
2) The maximum allowable power dissipation is a function of the maximum junction temperature $T_{J}(M A X)$, the junction-toambient thermal resistance $\theta_{\mathrm{jA}}$, and the ambient temperature $\mathrm{T}_{\mathrm{A}}$. The maximum allowable continuous power dissipation at any ambient temperature is calculated by $\mathrm{P}_{\mathrm{D}}(\mathrm{MAX})=\left(\mathrm{T}_{J}\right.$ (MAX)-TA $/ \theta_{\mathrm{JA}}$. Exceeding the maximum allowable power dissipation will cause excessive die temperature, and the regulator will go into thermal shutdown. Internal thermal shutdown circuitry protects the device from permanent damage.
3) The device is not guaranteed to function outside of its operating conditions.
4) Measured on JESD51-7, 4-layer PCB.

## ELECTRICAL CHARACTERISTICS

## PIN FUNCTIONS

| Package <br> Pin \# | Name | Description |
| :---: | :---: | :--- |
| 1 | SW | Switch Output |
| 2 | VIN | Power Supply Voltage. |
| 3 | VCC | Coarse Regulator Output. Internally generated 4.5V. Bypass with a 1 1 F capacitor to AGND. <br> Used to be low-side switch driver and pull-up bias voltage NTC resistive divider. Do not <br> connect any external load at this pin. |
| 4 | CELL | Keep the pin float or connect to GND. |
| 5 | SEL | Input Pin for Setting Terminal Battery Voltage: <br> SEL = Low-level or Float: $V_{\text {BATT }}=4.03 \mathrm{~V}$ <br> SEL $=$ High-level: $V_{\text {BATT }}=3.99 \mathrm{~V}$ |
| 6 | $\overline{\text { EN }}$ | On/ Off Control Input. This pin is pulled down to GND with a 1Meg internal resistor. |
| 7 | N/C | NO CONNECT. Please leave this pin floating. |
| 8 | AGND | Analog Ground. |
| 9 | BATT | Positive Battery Terminal. |
| 10 | CSP | Battery Current Sense Positive Input. Connect a resistor RS1 between CSP and BATT. |
| 11 | $\overline{\text { CHGOK }}$ | Charging Completion Indicator. A logic Low indicates charging operation. The pin will <br> become an open drain once the charge is completed or suspended. |
| 12 | $\overline{\text { ACOK }}$ | Valid Input Supply Indicator. A logic Low on this pin indicates the presence of a valid input <br> power supply. |
| 13 | NTC | Thermistor Input. Connect a resistor from this pin to the pin VCC and the thermistor from <br> this pin to ground. |
| 14 | TMR | Internal Safety Timer Control. Connect a capacitor from this node to AGND to set the timer. <br> And the timer can be disabled by connecting this pin to AGND directly. |
| 15 | BST | Bootstrap. This capacitor is needed to drive the power switch's gate above the supply <br> voltage. It is connected between SW and BST pins to form a floating supply across the <br> power switch driver. |
| 16 | PGND | Power Ground. |

## FUNCTIONAL BLOCK DIAGRAM

Figure 1: Functional Block Diagram

## OPERATION

The MP2615B is a peak current mode controlled switching charger for a 1 cell lithium-ion and lithium-polymer batteries. It integrates both the high-side and low-side switches of the synchronous BUCK converter, which provides high efficiency and saves the PCB space.

## Charge Cycle (Mode change: TC $\rightarrow$ CC $\rightarrow$ CV)

The MP2615B regulates the charge current (ICHG) and battery voltage ( $\mathrm{V}_{\text {BATT }}$ ) using two control loops to realize highly-accurate constant current (CC) charge and constant voltage (CV) charge.

As shown in Figure 2, when the $\mathrm{V}_{\mathrm{BATT}}<\mathrm{V}_{\mathrm{TC}}$, the MP2615B stays in trickle-charge mode and the output of charge current loop COMPI dominants the control. The battery is charged by a trickle charge current $I_{\text {TC }}$ until the battery voltage reaches $\mathrm{V}_{\mathrm{T} C}$. If the charger stays in the trickle-
charge mode till the trickle-charge timer is triggered, the charging will be terminated.

The MP2615B will enter constant-current charge mode once the battery voltage rises higher than $\mathrm{V}_{\mathrm{TC}}$, and in this mode the current loop continues dominating the control and the charge current will increase from $I_{T C}$ to $I_{C C}$ to fast charge the battery

When the battery voltage rises over full battery voltage $\mathrm{V}_{\text {BAtt_full, }}$ the charger enters into constant-voltage mode. In constant voltage mode, the battery voltage is regulated at $\mathrm{V}_{\text {BATt_FULL }}$ precisely and the charge current will fall naturally due to the existing equivalent internal resistance of the battery. For the operation flow chart, please also refer to Figure 4.

Figure 2: Li-ion Battery Charge Profile

## Charge Full Termination and Auto-Recharge

When the charge current drops below the termination threshold ( $\mathrm{I}_{\mathrm{BF}}$ ) during the CV charge phase, the charger will stop charging and the $\overline{\text { CHGOK }}$ pin becomes open drain. The timer will also be reset and turned off. Once the battery voltage decrease below the recharge threshold $\mathrm{V}_{\mathrm{RECH}}$, recharging will automatically kick in and the timer restarts a new charge cycle.

## COT Charge Mode

MP2615B uses the floating ground method to drive the high-side MOSFET of the buck converter. During the off-time of the high-side MOSFET, the BST capacitor is recharged and the voltage across it is used as the HS-MOS gate drive. Thus a minimum off-time 200ns is required to maintain sufficient voltage at BST capacitor.
When the 200 ns minimum off-time is achieved due to a large duty cycle, the MP2615B enters into the COT (constant off-time) charge mode. In this mode of operation, Switching frequency is decreased in order to achieve up to $99 \%$ duty cycle.

## Charge Status Indication

MP2615B has two open-drain status outputs, $\overline{\mathrm{CHGOK}}$ pin and $\overline{\mathrm{ACOK}}$ pin. The $\overline{\mathrm{ACOK}}$ pin goes low when the input voltage is 300 mV larger than battery voltage and over the under voltage lockout threshold. Pin $\overline{\mathrm{CHGOK}}$ is used to indicate the status of the charge cycle. Table 1 summarized the operation of both $\overline{\mathrm{CHGOK}}$ and $\overline{\mathrm{ACOK}}$ according to the status of charge.

Table 1: Charging Status Indication

| $\overline{\text { ACOK }}$ | $\overline{\text { CHGOK }}$ | Charger Status |
| :---: | :---: | :---: |
| Low | Low | In charging |
| Low | High impedance | End of charge; NTC fault; <br> Timer out; <br> EN disable; <br> Thermal shutdown; |
| High impedance | High impedance | $\mathrm{V}_{\text {IN }}$ absent; $V_{I N}-V_{\text {BATT }}<0.3 \mathrm{~V}$ |

and GND is used to set the internal oscillator period,

$$
\begin{equation*}
\mathrm{T}_{\mathrm{P}}(\text { seconds })=0.46 \times \mathrm{C}_{\text {TMR }}(\mathrm{uF}) \tag{1}
\end{equation*}
$$

This timer limits the max trickle charge time to 8192 internal oscillating period. If the charger stays in trickle charge mode for longer than the max oscillating periods, it will be terminated and the $\overline{\mathrm{CHGOK}}$ becomes open drain to indicate the timer-out fault. If the charge successfully goes through trickle charge within the allowed time limit, it enters into the CC charge mode and the timer continues to count the oscillating periods. When the battery is charged full, the timer turns off and clears the counter, waiting for the autorecharge to restart.
If the charge time during CC/CV mode exceeds 49152 oscillating periods and the battery full has not been qualified, the charger will be terminated and a timer-out fault is also indicated by floating the $\overline{\mathrm{CHGOK}}$. The charger can exit the timer-out fault state and the on-chip safety timer restarts counting when one of the following conditions occurs:

- The battery voltage falls below the autorecharge threshold $\mathrm{V}_{\text {RECH }}$.
- A power-on-reset (POR) event occurs;
- $\overline{\mathrm{EN}}$ pin is toggled.

The timer can be disabled by pulling TMR-pin to AGND.

Thus, the trickle mode charge time is:

$$
\begin{equation*}
\mathrm{t}_{\text {Trickle_tmr }}(\text { minutes })=62.8 \times \mathrm{C}_{\text {TMR }}(\mathrm{uF}) \tag{2}
\end{equation*}
$$

If connect a $\mathrm{C}_{\text {TMR }}$ of 0.47 uF , the trickle charge time is about 30 minutes.

The CC/CV mode charge time is:

$$
\begin{equation*}
\mathrm{t}_{\text {Total_tmr }}(\text { hours })=6.28 \times \mathrm{C}_{\text {TMR }}(\mathrm{uF}) \tag{3}
\end{equation*}
$$

If connect a $\mathrm{C}_{\text {TMR }}$ of 0.47 uF , the $\mathrm{CC} / \mathrm{CV}$ charge time is 2.95 hours.

## Safety Timer Operation

The MP2615B has an internal safety timer to terminate charging if the timer times out. The capacitor $\mathrm{C}_{\text {TMR }}$ connected between the TMR pin

## Negative Thermal Coefficient (NTC) Thermistor

The NTC pin allows MP2615B to sense the battery temperature using the Negative Thermal Coefficient (NTC) resistor available in the battery pack to ensure safe operating environment of the battery. A resistor with appropriate value should be connected from VCC to NTC pin and the thermistor is connected from NTC pin to AGND. The voltage on NTC-pin is determined by the resistor divider whose divide-ratio depends on the battery temperature. When the voltage at NTC pin falls out of the NTC window range, the charging will pause until battery temperature goes back into the normal operation conditions
As a result the MP2615B will stop charging and report this condition to the status pins, the timer will also be suspended but will continue counting from where they left off when charging resumes.

## Short Circuit Protection

The MP2615B has an internal comparator to check for battery short circuit. Once $\mathrm{V}_{\text {BAtt }}$ falls below 2 V , the device detects a battery-short status and the cycle-by-cycle peak current limit falls to about 2.2A to limit the current spike during the battery-short transition. Furthermore, the switching frequency also folds back to minimize the power loss.

## Thermal Shutdown Protection

To prevent the chip from overheating during charging, the MP2615B monitors the junction temperature, $T_{\jmath}$, of the die. Once $T_{\jmath}$ reaches the thermal shutdown threshold ( $\mathrm{T}_{\text {SHTDWN }}$ ) of $150^{\circ} \mathrm{C}$, the charger converter turns off. Once the $T_{J}$ falls below $130^{\circ} \mathrm{C}$ the charging will restart.

INPUT POWER UP START UP TIMING FLOW

Figure 3: Input Power Start-up Timing Diagram

OPERATION FLOW CHART

Figure 4: Operation Flow Chart

## APPLICATION INFORMATION

## COMPONENT SELECTION

## Charge Current Setting

The constant charge current ( $\mathrm{I}_{\mathrm{cc}}$ ) of MP2615B can be set by the sense resistor RS1 (see Typical Application). The equation to determine the programmable CC-charge current is expressed as following,

$$
\begin{equation*}
I_{c c}=\frac{100 \mathrm{mV}}{\mathrm{RS} 1(\mathrm{~m} \Omega)}(\mathrm{A}) \tag{4}
\end{equation*}
$$

To get $2 \mathrm{~A} \mathrm{I}_{\mathrm{cc}}$, a RS1 of $50 \mathrm{~m} \Omega$ should be selected. Accordingly, the trickle charge current (lic) can be obtained by the following equation,

$$
\begin{equation*}
\mathrm{I}_{\mathrm{TC}}=10 \% \mathrm{I}_{\mathrm{CC}}=\frac{10 \mathrm{mV}}{\mathrm{RS} 1(\mathrm{~m} \Omega)}(\mathrm{A}) \tag{5}
\end{equation*}
$$

## Inductor Selection

For inductor selection, a trade off should be made between cost, size, and efficiency. An inductor of lower inductance value corresponds with smaller size, but results in higher ripple currents, higher magnetic hysteretic losses, and higher output capacitances. Conversely, higher inductance value is beneficial to getting a lower ripple current and smaller output filter capacitors, but resulting in higher inductor DC resistance (DCR) loss. According to the practical experience, the inductor ripple current should not exceed $15 \%$ of the maximum charge current under worst cases. For a MP2615B with a typical 12V input voltage to charge a 1-cell battery, the maximum inductor current ripple occurs at the corner point between trickle charge and CC charge ( $\mathrm{V}_{\text {BATT }}=$ 3 V ). Estimate the required inductance as:

$$
\begin{equation*}
\mathrm{L}=\frac{\mathrm{V}_{\mathrm{IN}}-\mathrm{V}_{\mathrm{BATT}}}{\Delta \mathrm{I}_{\mathrm{L}-\mathrm{MAX}}} \frac{\mathrm{~V}_{\text {BATT }}}{\mathrm{V}_{\text {IN }} \cdot f_{\mathrm{S}}} \tag{6}
\end{equation*}
$$

where $V_{I N}, V_{\text {BATT }}$, and $f_{S}$ are the typical input voltage, the CC charge threshold, and the switching frequency, respectively. And $\Delta \mathrm{I}_{\mathrm{L}_{-} \text {max }}$ is the maximum inductor ripple current, which is usually $30 \%$ of the CC charge current.

$$
\begin{equation*}
\Delta \mathrm{I}_{\mathrm{L}-\mathrm{MAX}}=30 \% \mathrm{I}_{\mathrm{CC}} \tag{7}
\end{equation*}
$$

For the condition that $\mathrm{I}_{\mathrm{CC}}=2 \mathrm{~A}, \mathrm{~V}_{\mathrm{IN}}=12 \mathrm{~V}, \mathrm{~V}_{\mathrm{BATT}}=$ 3 V and $\mathrm{f}_{\mathrm{s}}=760 \mathrm{kHz}$ the calculated inductance is $4.93 \mu \mathrm{H}$. The inductor saturant current must exceed 2.6A at least and have some tolerance.

To optimize efficiency, chose an inductor with a DC resistance less than $50 \mathrm{~m} \Omega$.

## NTC Resistor Divider Selection

Figure 5 shows that an internal resistor divider sets the low temperature threshold and high temperature threshold at $73.3 \% \cdot$ VCC and $29.3 \% \cdot$ VCC, respectively. For a given NTC

Figure 5: NTC Function Block
thermistor, select appropriate $\mathrm{R}_{\mathrm{T} 1}$ and $\mathrm{R}_{\mathrm{T} 2}$ to set the NTC window.
The thermistor (NCP18XH103) noted above has the following electrical characteristic:

- At $0^{\circ} \mathrm{C}, R_{\text {NTC_Cold }}=27.445 \mathrm{k} \Omega$;
- At $50^{\circ} \mathrm{C}, \mathrm{R}_{\text {NTC_Hot }}=4.1601 \mathrm{k} \Omega$.

The following equations are derived assuming that the NTC window is between $0^{\circ} \mathrm{C}$ and $50^{\circ} \mathrm{C}$ :

$$
\begin{gather*}
\frac{\mathrm{R}_{\mathrm{T} 2} / / R_{\text {NTC_cold }}}{\mathrm{R}_{\mathrm{T} 1}+\mathrm{R}_{\mathrm{T} 2} / / R_{\text {NTC_Cold }}}=\frac{\mathrm{V}_{\text {TH_Low }}}{\text { VREF33 }}=73.3 \%  \tag{8}\\
\frac{\mathrm{R}_{\mathrm{T} 2} / / \mathrm{R}_{\text {NTC_Hot }}}{\mathrm{R}_{\mathrm{T} 1}+\mathrm{R}_{\mathrm{T} 2} / / \mathrm{R}_{\text {NTC_Hot }}}=\frac{\mathrm{V}_{\text {TH_High }}}{\text { VREF33 }}=29.3 \% \tag{9}
\end{gather*}
$$

According to Equation (8) (9), and the required battery temperature range to calculate $\mathrm{R}_{\mathrm{T} 1}$ and $\mathrm{R}_{\mathrm{T} 2}$.

## Input Capacitor Selection

The input capacitors C1 from the typical application circuit absorbs the maximum ripple current from the buck converter, which is given by:

$$
\begin{equation*}
I_{\text {RMS_MAX }}=I_{\mathrm{CC}} \frac{\sqrt{\mathrm{~V}_{\mathrm{TC}}\left(\mathrm{~V}_{\text {IN_MAX }} \mathrm{V}_{\mathrm{TC}}\right)}}{\mathrm{V}_{\text {IN_MAX }}} \tag{10}
\end{equation*}
$$

For a given $\mathrm{I}_{\mathrm{CC}}=2 \mathrm{~A}, \mathrm{~V}_{\mathrm{TC}}=3 \mathrm{~V}, \mathrm{~V}_{\mathrm{IN}_{\text {_max }}}=18 \mathrm{~V}$, the maximum ripple current is 1 A . Select the input capacitors so that the temperature rise due to the ripple current does not exceed $10^{\circ} \mathrm{C}$. Use ceramic capacitors with X5R or X7R dielectrics because of their low ESR and small temperature coefficients. For most applications, use a $22 \mu \mathrm{~F}$ capacitor.

## Output Capacitor Selection

The output capacitor C2 (see the typical application circuit) is in parallel with the battery. C2 absorbs the high-frequency switching ripple current and smoothes the output voltage. Its impedance must be much less than that of the battery to ensure it absorbs the ripple current. Use a ceramic capacitor because it has lower ESR and smaller size that allows us to ignore the ESR of the output capacitor. Thus, the output voltage ripple is given by,

$$
\begin{equation*}
\Delta r_{\mathrm{O}}=\frac{\Delta \mathrm{V}_{\mathrm{O}}}{\mathrm{~V}_{\mathrm{O}}}=\frac{1-\frac{\mathrm{V}_{\mathrm{O}}}{\mathrm{~V}_{\mathrm{IN}}}}{8 \mathrm{C}_{\mathrm{O}} \mathrm{f}_{\mathrm{s}}^{2} \mathrm{~L}} \tag{11}
\end{equation*}
$$

In order to guarantee the $\pm 0.5 \%$ full battery voltage accuracy, the maximum output voltage ripple must not exceed 0.5\% (e.g.0.1\%). The maximum output voltage ripple occurs at the minimum battery voltage of the CC charge and the maximum input voltage.

For $\mathrm{V}_{\text {IN_max }}=18 \mathrm{~V}, \mathrm{~V}_{\text {CC_MIN }}=\mathrm{V}_{\mathrm{TC}}=3 \mathrm{~V}, \mathrm{~L}=4.7 \mu \mathrm{H}$, $\mathrm{f}_{\mathrm{S}}=760 \mathrm{kHz}, \Delta \mathrm{R}_{\mathrm{O} \text { _MAX }}=0.2 \%$, the output capacitor can be calculated as,

$$
\begin{equation*}
C_{0}=\frac{1-\frac{V_{\text {TC }}}{V_{\mathrm{IN}_{-} \operatorname{MAX}}}}{8 \mathrm{f}_{\mathrm{s}}^{2} L \Delta \mathrm{r}_{0_{-} \mathrm{MAX}}}=19.2(\mu F) \tag{12}
\end{equation*}
$$

We can then choose a $22 \mu \mathrm{~F}$ ceramic capacitor.

## PCB Layout Guide

PCB layout is important to meet specified noise, efficiency and stability requirements. The following design considerations can improve circuit performance,

1) Route the power stage adjacent to their grounds. Aim to minimize the high-side switching node (SW, inductor), trace lengths in the high-current paths and the current-sense resistor trace. Keep the switching node short and away from the feedback network.
2) Connect the charge current sense resistor to CSP (pin 10), BATT (pin 9). Minimize the length and area of this circuit loop.
3) Place the input capacitor as close as possible to the VIN and PGND pins. Place the output inductor close to the IC as and connect the output capacitor between the inductor and PGND of the IC. This minimizes the current path loop area from the SW pin through the LC filter and back to the PGND pin.
4) Connect AGND and PGND at a single point.
5) Figure 6 is a PCB layout reference design.
