1.0	300302-001	Initial release	January 2004

1 Introduction

The Intel® Celeron® M processor and the ultra low voltage (ULV) Intel® Celeron® M processor are high-performance, low-power mobile processors with several microarchitectural enhancements over existing mobile Intel Celeron processors.

The Intel Celeron M processor is available at the following core frequencies in the Micro-FCBGA and Micro-FCPGA packaging technologies:

- 1.20 GHz (1.356 V)
- 1.30 GHz (1.356 V)

The ultra low voltage Intel Celeron M processor is available at the following frequency in the Micro-FCBGA packaging technology:

- 800 MHz (1.004 V)

The Micro-FCPGA package plugs into a 479-hole, surface-mount, zero insertion force (ZIF) socket, which is referred to as the mPGA479M socket.

The following list provides some of the key features of this processor:

- Supports Intel architecture with dynamic execution
- Manufactured on Intel's advanced 0.13 micron process technology with copper interconnect.
- High-performance, low-power core featuring architectural innovations like micro-ops fusion and advanced stack management that reduce the number of micro-ops handled by the processor.
- On-die, primary 32-kB instruction cache and 32-kB, write-back, data cache
- On-die, 512-kB second level cache with Advanced Transfer Cache architecture
- Advanced branch prediction and data prefetch logic
- Streaming SIMD extensions 2 (SSE2) that enables breakthrough levels of performance in multimedia applications including 3D graphics, video decoding/encoding, and speech recognition.
- 400-MHz, source-synchronous front side bus (FSB)
- Advanced power management features
- Maintained support for MMX™ technology
- Compatible with IA-32 software.

The processor also features a very advanced branch prediction architecture that significantly reduces the number of mispredicted branches. The processor's Data Prefetch Logic speculatively fetches data to the L2 cache before an L1 cache request occurs, resulting in reduced bus cycle penalties and improved performance.

The new packed, double-precision, floating-point instructions enhance performance for applications that require greater range and precision, including scientific and engineering applications and advanced 3D geometry techniques, such as ray tracing.

The processor's 400-MHz FSB utilizes a split-transaction, deferred reply protocol. The 400-MHz FSB uses source-synchronous transfer (SST) of address and data to improve performance by transferring data four times per bus clock (4X data transfer rate, as in AGP 4X). Along with the 4X data bus, the address bus can deliver addresses two times per bus clock and is referred to as a "double-clocked" or 2X address bus. Working together, the 4X data bus and 2X address bus provide a data bus bandwidth of up to 3.2 GB/second. The FSB uses Advanced Gunning Transceiver Logic (AGTL+) signal technology, a variant of GTL+ signalling technology with low power enhancements.

Note: The term AGTL+ has been used for Assisted Gunning Transceiver Logic technology on other Intel products.

1.1 Terminology

Term	Definition
#	A "#" symbol after a signal name refers to an active low signal, indicating a signal is in the active state when driven to a low level. For example, when RESET# is low, a reset has been requested. Conversely, when NMI is high, a nonmaskable interrupt has occurred. In the case of signals where the name does not imply an active state but describes part of a binary sequence (such as *address* or *data*), the "#" symbol implies that the signal is inverted. For example, D[3:0] = "HLHL" refers to a hex "A", and D[3:0]# = "LHLH" also refers to a hex "A" (H= High logic level, L= Low logic level).
FSB	Front Side Bus refers to the interface between the processor and system core logic (also known as the chipset components).

1.3 State of Data

The data contained within this document represents the most accurate information available by the publication date. However, all data in this document is preliminary and subject to change.

This page intentionally left blank.

2 Low Power Features

2.1 Clock Control and Low Power States

The Intel Celeron M processor supports the AutoHALT, Stop Grant, Sleep, and Deep Sleep states for optimal power management. See Figure 1 for a visual representation of the processor low-power states.

2.1.1 Normal State

This is the normal operating state for the processor.

2.1.2 AutoHALT Power-Down State

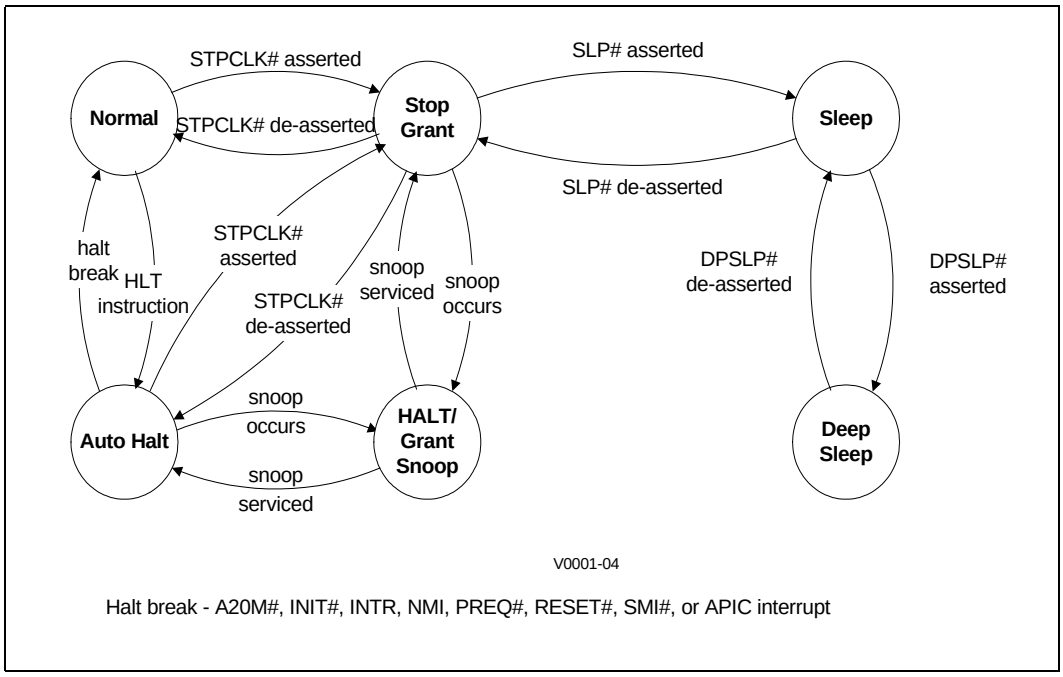
AutoHALT is a low-power state entered when the processor executes the HALT instruction. The processor will transition to the Normal state upon the occurrence of SMI#, INIT#, LINT[1:0] (NMI, INTR), or FSB interrupt message. RESET# will cause the processor to immediately initialize itself.

The return from a System Management Interrupt (SMI) handler can be to either Normal mode or the AutoHALT Power-Down state. See the *Intel Architecture Software Developer's Manual, Volume III: System Programmer's Guide* for more information.

The system can generate a STPCLK# while the processor is in the AutoHALT Power-Down state. When the system deasserts the STPCLK# interrupt, the processor will return execution to the HALT state.

While in AutoHALT Power-Down state, the processor will process bus snoops.

Figure 1. Clock Control States



2.1.3 Stop-Grant State

When the STPCLK# pin is asserted, the Stop-Grant state of the processor is entered 20 bus clocks after the response phase of the processor issued Stop-Grant Acknowledge special bus cycle.

Since the AGTL+ signal pins receive power from the FSB, these pins should not be driven (allowing the level to return to V_{CCP}) for minimum power drawn by the termination resistors in this state. In addition, all other input pins on the FSB should be driven to the inactive state.

RESET# will cause the processor to immediately initialize itself, but the processor will stay in Stop-Grant state. A transition back to the Normal state will occur with the deassertion of the STPCLK# signal. When re-entering the Stop-Grant state from the Sleep state, STPCLK# should be deasserted ten or more bus clocks after the deassertion of SLP#.

A transition to the HALT/Grant Snoop state will occur when the processor detects a snoop on the FSB (see Section 2.1.4). A transition to the Sleep state (see Section 2.1.5) will occur with the assertion of the SLP# signal.

While in the Stop-Grant State, SMI#, INIT# and LINT[1:0] will be latched by the processor, and only serviced when the processor returns to the Normal State. Only one occurrence of each event will be recognized upon return to the Normal state. Please refer to the FERR# pin description in Section 4.2 for details on FERR# break event behavior in the Stop Grant state.

While in Stop-Grant state, the processor will process snoops on the FSB and it will latch interrupts delivered on the FSB.

The PBE# signal can be driven when the processor is in Stop-Grant state. PBE# will be asserted if there is any pending interrupt latched within the processor. Pending interrupts that are blocked by the EFLAGS.IF bit being clear will still cause assertion of PBE#. Assertion of PBE# indicates to system logic that it should return the processor to the Normal state.

2.1.4 HALT/Grant Snoop State

The processor will respond to snoop or interrupt transactions on the FSB while in Stop-Grant state or in AutoHALT Power-Down state. During a snoop or interrupt transaction, the processor enters the HALT/Grant Snoop state. The processor will stay in this state until the snoop on the FSB has been serviced (whether by the processor or another agent on the FSB) or the interrupt has been latched. After the snoop is serviced or the interrupt is latched, the processor will return to the Stop-Grant state or AutoHALT Power-Down state, as appropriate.

2.1.5 Sleep State

The Sleep state is a low-power state in which the processor maintains its context, maintains the phase-locked loop (PLL), and has stopped all internal clocks. The Sleep state can only be entered from Stop-Grant state. Once in the Stop-Grant state, the processor will enter the Sleep state upon the assertion of the SLP# signal. The SLP# pin should only be asserted when the processor is in the Stop Grant state. SLP# assertions while the processor is not in the Stop-Grant state is out of specification and may result in unapproved operation.

Snoop events that occur while in Sleep State or during a transition into or out of Sleep state will cause unpredictable behavior.

In the Sleep state, the processor is incapable of responding to snoop transactions or latching interrupt signals. No transitions or assertions of signals (with the exception of SLP#, DPSLP# or RESET#) are allowed on the FSB while the processor is in Sleep state. Any transition on an input signal before the processor has returned to Stop-Grant state will result in unpredictable behavior.

If RESET# is driven active while the processor is in the Sleep state, and held active as specified in the RESET# pin specification, then the processor will reset itself, ignoring the transition through Stop-Grant State. If RESET# is driven active while the processor is in the Sleep State, the SLP# and STPCLK# signals should be deasserted immediately after RESET# is asserted to ensure the processor correctly executes the Reset sequence.

While in the Sleep state, the processor is capable of entering an even lower power state, the Deep Sleep state by asserting the DPSLP# pin. (see Section 2.1.6.). While the processor is in the Sleep state, the SLP# pin must be deasserted if another asynchronous FSB event needs to occur.

2.1.6 Deep Sleep State

Deep Sleep state is a very low-power state the processor can enter while maintaining context. Deep Sleep state is entered by asserting the DPSLP# pin while in the Sleep state. BCLK may be stopped during the Deep Sleep state for additional platform-level power savings. BCLK stop/restart timings on Intel 855PM/ICH4-M, Intel 855GM/ICH4-M, and Intel 852GM/ICH4-M chipset-based platforms with the CK-408 clock chip are as follows:

- Deep Sleep entry - DPSLP# and CPU_STP# are asserted simultaneously. CK-408 will stop/tristate BCLK within 2 BCLKs +/- a few nanoseconds.

- Deep Sleep exit - DPSLP# and CPU_STP# are deasserted simultaneously. CK-408 will drive BCLK to differential DC levels within 2-3 ns and starts toggling BCLK 2-6 BCLK periods later.

To re-enter the Sleep state, the DPSLP# pin must be deasserted. BCLK can be restarted after DPSLP# deassertion as described above. A period of 30 microseconds (to allow for PLL stabilization) must occur before the processor can be considered to be in the Sleep State. Once in the Sleep state, the SLP# pin must be deasserted to re-enter the Stop-Grant state.

While in Deep Sleep state, the processor is incapable of responding to snoop transactions or latching interrupt signals. No transitions of signals are allowed on the FSB while the processor is in Deep Sleep state. Any transition on an input signal before the processor has returned to Stop-Grant state will result in unpredictable behavior.

When the processor is in Deep Sleep state, it will not respond to interrupts or snoop transactions.

2.2 FSB Low Power Enhancements

The Intel Celeron M processor incorporates the following FSB low power enhancements:

- Dynamic FSB power-down
- BPRI# control for address and control input buffers
- Dynamic on-die termination disabling
- Low VCCP (I/O termination voltage)

The Intel Celeron M processor incorporates the DPWR# signal that controls the data bus input buffers on the processor. The DPWR# signal disables the buffers when not used and activates them only when data bus activity occurs, resulting in significant power savings with no performance impact. BPRI# control also allows the processor address and control input buffers to be turned off when the BPRI# signal is inactive. The On-Die termination on the processor FSB buffers is disabled when the signals are driven low, resulting in additional power savings. The low I/O termination voltage is on a dedicated voltage plane independent of the core voltage, enabling low I/O switching power at all times.

2.3 Processor Power Status Indicator (PSI#) Signal

The Intel Celeron M processor incorporates the PSI# signal that is asserted when the processor is in a low power (Deep Sleep) state. This signal is asserted upon Deep Sleep entry and deasserted upon exit. PSI# can be used to improve the light load efficiency of the voltage regulator, resulting in platform power savings and extended battery life.

3 Electrical Specifications

3.1 FSB and GTLREF

The Intel Celeron M processor FSB uses Advanced Gunning Transceiver Logic (AGTL+) signalling technology, a variant of GTL+ signalling technology with low power enhancements. This signalling technology provides improved noise margins and reduced ringing through low-voltage swings and controlled edge rates. The termination voltage level for the Intel Celeron M processor AGTL+ signals is VCCP = 1.05 V (nominal). Due to speed improvements to data and address bus, signal integrity and platform design methods have become more critical than with previous processor families. Design guidelines for the Intel Celeron M processor FSB will be detailed in the platform design guides.

The AGTL+ inputs require a reference voltage (GTLREF) that is used by the receivers to determine if a signal is a logical 0 or a logical 1. GTLREF must be generated on the system board. Termination resistors are provided on the processor silicon and are terminated to its I/O voltage (VCCP). Intel's 855PM, 855GM, and 852GM chipsets will also provide on-die termination, thus eliminating the need to terminate the bus on the system board for most AGTL+ signals.

Refer to the platform design guides for board level termination resistor requirements.

The AGTL+ bus depends on incident wave switching. Therefore, timing calculations for AGTL+ signals are based on flight time as opposed to capacitive deratings. Analog signal simulation of the FSB, including trace lengths, is highly recommended when designing a system.

3.2 Power and Ground Pins

For clean on-chip power distribution, the Intel Celeron M processor will have a large number of V_{CC} (power) and V_{SS} (ground) inputs. All power pins must be connected to V_{CC} power planes while all V_{SS} pins must be connected to system ground planes. Use of multiple power and ground planes is recommended to reduce I x R drop. Please refer to the platform design guides for more details. The processor V_{CC} pins must be supplied the voltage determined by the VID (Voltage ID) pins.

3.3 Decoupling Guidelines

Due to its large number of transistors and high internal clock speeds, the processor is capable of generating large average current swings between low- and full-power states. This may cause voltages on power planes to sag below their minimum values if bulk decoupling is not adequate. Care must be taken in the board design to ensure that the voltage provided to the processor remains within the specifications listed in Table 5. Failure to do so can result in timing violations or reduced lifetime of the component. For further information and design guidelines, refer to the platform design guides.

3.3.1 V_{CC} Decoupling

Regulator solutions need to provide bulk capacitance with a low effective series resistance (ESR) and keep a low interconnect resistance from the regulator to the socket. Bulk decoupling for the large current swings when the part is powering on, or entering/exiting low-power states, must be provided by the voltage regulator solution. For more details on decoupling recommendations, please refer to the platform design guides. Intel **strongly recommends** that the layout and decoupling recommendations in the platform design guides be followed.

3.3.2 FSB AGTL+ Decoupling

Intel Celeron M processors integrate signal termination on the die as well as incorporate high-frequency decoupling capacitance on the processor package. Decoupling must also be provided by the system motherboard for proper AGTL+ bus operation. For more information, refer to the platform design guides.

3.3.3 FSB Clock (BCLK[1:0]) and Processor Clocking

BCLK[1:0] directly controls the FSB interface speed as well as the core frequency of the processor. As in previous generation processors, the Intel Celeron M processor core frequency is a multiple of the BCLK[1:0] frequency. In regards to processor clocking, the Intel Celeron M processor uses a differential clocking implementation.

3.4 Voltage Identification

The processor uses six voltage identification pins, VID[5:0], to support automatic selection of power supply voltages. The VID pins for the processor are CMOS outputs driven by the processor VID circuitry. Table 2 specifies the voltage level corresponding to the state of VID[5:0]. A 1 in this refers to a high-voltage level and a 0 refers to low-voltage level.

Table 2. Voltage Identification Definition

VID						V_{CC} V	VID						V_{CC} V

0	1	1	1	1	1	1.212	1	1	1	1	1	1	0.700

3.5 Catastrophic Thermal Protection

The processor supports the THERMTRIP# signal for catastrophic thermal protection. An external thermal sensor should also be used to protect the processor and the system against excessive temperatures. Even with the activation of THERMTRIP#, which halts all processor internal clocks and activity, leakage current can be high enough such that the processor cannot be protected in all conditions without the removal of power to the processor. If the external thermal sensor detects a catastrophic processor temperature of 125 °C (maximum), or if the THERMTRIP# signal is asserted, the VCC supply to the processor must be turned off within
500 ms to prevent permanent silicon damage due to thermal runaway of the processor.

3.6 Signal Terminations and Unused Pins

All RSVD (RESERVED) pins must remain unconnected. Connection of these pins to V_{CC}, V_{SS}, or to any other signal (including each other) can result in component malfunction or incompatibility with future Intel Celeron M processors. See Section 4.1 for a pin listing of the processor and the location of all RSVD pins.

For reliable operation, always connect unused inputs or bidirectional signals to an appropriate signal level. Unused active low AGTL+ inputs may be left as no connects if AGTL+ termination is provided on the processor silicon. Unused active high inputs should be connected through a resistor to ground (V_{SS}). Unused outputs can be left unconnected.

For details on signal terminations, please refer to the platform design guides. TAP signal termination requirements are also discussed in *ITP700 Debug Port Design Guide*.

The TEST1, TEST2, and TEST3 pins must be left unconnected but should have a stuffing option connection to V_{SS} separately via 1-kΩ, pull-down resistors.

3.7 FSB Signal Groups

In order to simplify the following discussion, the FSB signals have been combined into groups by buffer type. AGTL+ input signals have differential input buffers, which use GTLREF as a reference level. In this document, the term "AGTL+ Input" refers to the AGTL+ input group as well as the AGTL+ I/O group when receiving. Similarly, "AGTL+ Output" refers to the AGTL+ output group as well as the AGTL+ I/O group when driving.

With the implementation of a source synchronous data bus comes the need to specify two sets of timing parameters. One set is for common clock signals which are dependant upon the crossing of the rising edge of BCLK0 and the falling edge of BCLK1. The second set is for the source synchronous signals which are relative to their respective strobe lines (data and address) as well as the rising edge of BCLK0. Asychronous signals are still present (A20M#, IGNNE#, etc.) and can become active at any time during the clock cycle. Table 3 identifies which signals are common clock, source synchronous, and asynchronous.

Table 3. FSB Pin Groups

Signal Group	Type	Signals[1]
AGTL+ Common Clock Input	Synchronous to BCLK[1:0]	BPRI#, DEFER#, DPWR#, PREQ#, RESET#, RS[2:0]#, TRDY#
AGTL+ Common Clock I/O	Synchronous to BCLK[1:0]	ADS#, BNR#, BPM[3:0]#[2], BR0#, DBSY#, DRDY#, HIT#, HITM#, LOCK#, PRDY#[2]
AGTL+ Source Synchronous I/O	Synchronous to assoc. strobe	<table><tr><th>Signals</th><th>Associated Strobe</th></tr><tr><td>REQ[4:0]#, A[16:3]#</td><td>ADSTB[0]#</td></tr><tr><td>A[31:17]#</td><td>ADSTB[1]#</td></tr><tr><td>D[15:0]#, DINV0#</td><td>DSTBP0#, DSTBN0#</td></tr><tr><td>D[31:16]#, DINV1#</td><td>DSTBP1#, DSTBN1#</td></tr><tr><td>D[47:32]#, DINV2#</td><td>DSTBP2#, DSTBN2#</td></tr><tr><td>D[63:48]#, DINV3#</td><td>DSTBP3#, DSTBN3#</td></tr></table>
AGTL+ Strobes	Synchronous to BCLK[1:0]	ADSTB[1:0]#, DSTBP[3:0]#, DSTBN[3:0]#
CMOS Input	Asynchronous	A20M#, DPSLP#, IGNNE#, INIT#, LINT0/INTR, LINT1/NMI, PWRGOOD, SMI#, SLP#, STPCLK#
Open Drain Output	Asynchronous	FERR#, IERR#, PROCHOT#, THERMTRIP#
CMOS Output	Asynchronous	PSI#, VID[5:0]
CMOS Input	Synchronous to TCK	TCK, TDI, TMS, TRST#
Open Drain Output	Synchronous to TCK	TDO
FSB Clock	Clock	BCLK[1:0], ITP_CLK[1:0][3]
Power/Other		COMP[3:0], DBR#[3], GTLREF, RSVD, TEST3, TEST2, TEST1, THERMDA, THERMDC, V_{CC}, V_{CCA}[3:0], V_{CCP}, V_{CCQ}[1:0], V_{CC_SENSE}, V_{SS}, V_{SS_SENSE}

NOTES:
1. Refer to Chapter 4 for signal descriptions and termination requirements.
2. BPM[2:0]# and PRDY# are AGTL+ output only signals.
3. In processor systems where there is no debug port implemented on the system board, these signals are used to support a debug port interposer. In systems with the debug port implemented on the system board, these signals are no connects.

3.8 CMOS Signals

CMOS input signals are shown in Table 3. Legacy output FERR#, IERR# and other non-AGTL+ signals (THERMTRIP# and PROCHOT#) utilize Open Drain output buffers. These signals do not have setup or hold time specifications in relation to BCLK[1:0]. However, all of the CMOS signals are required to be asserted for at least three BCLKs in order for the chipset to recognize them. See Section 3.10 for the DC specifications for the CMOS signal groups.

3.9 Maximum Ratings

Table 4 lists the processor's maximum environmental stress ratings. The processor should not receive a clock while subjected to these conditions. Functional operating parameters are listed in the AC and DC tables. Extended exposure to the maximum ratings may affect device reliability. Furthermore, although the processor contains protective circuitry to resist damage from electro static discharge (ESD), system designers should always take precautions to avoid high-static voltages or electric fields.

Table 4. Processor DC Absolute Maximum Ratings

Symbol	Parameter	Min	Max	Unit	Notes
$T_{STORAGE}$	Processor storage temperature	–40	85	°C	2
V_{CC}	Any processor supply voltage with respect to V_{SS}	-0.3	1.75	V	1
$V_{inAGTL+}$	AGTL+ buffer DC input voltage with respect to V_{SS}	-0.1	1.75	V	1, 2
$V_{inAsynch\_CMOS}$	CMOS buffer DC input voltage with respect to V_{SS}	-0.1	1.75	V	1, 2

NOTES:
1. This rating applies to any processor pin.
2. Contact Intel for storage requirements in excess of one year.

3.10 Processor DC Specifications

The processor DC specifications in this section are defined at the processor core (pads) unless noted otherwise. See Table 11 for the pin signal definitions and signal pin assignments. Most of the signals on the FSB are in the AGTL+ signal group. The DC specifications for these signals are listed in Table 11. DC specifications for the CMOS group are listed in Table 12.

Table 5 through Table 13 list the DC specifications for the Intel Celeron M processor and are valid only while meeting specifications for junction temperature, clock frequency, and input voltages. Active Mode load line specifications apply in all states except in the Deep Sleep state. $V_{CC,BOOT}$ is the default voltage driven by the voltage regulator at power up in order to set the VID values. Unless specified otherwise, all specifications for the Intel Celeron M processor are at Tjunction = 100 °C. Care should be taken to read all notes associated with each parameter.

Table 5. Voltage and Current Specifications

Symbol	Parameter	Min	Typ	Max	Unit	Notes
V_{CC}	Intel Celeron M processor 1.20 GHz Core V_{CC} 1.30 GHz Core V_{CC} Ultra low voltage Intel Celeron M Processor 800 MHz Core Vcc		 1.356 1.356 1.004		V	1, 2

I_{CCP}	I_{CC} for V_{CCP} supply			2.5	A	

NOTES:
1. The typical values shown are the VID encoded voltages. Static and Ripple tolerances (for minimum and maximum voltages) are defined in the load line tables Table 6, Table 7, Table 8, and Table 9 .
2. The voltage specifications are assumed to be measured at a via on the motherboard's opposite side of the processor's socket (or BGA) ball with a 100-MHz bandwidth oscilloscope, 1.5-pF maximum probe capacitance, and 1-Mohm minimum impedance. The maximum length of ground wire on the probe should be less than 5 mm. Ensure external noise from the system is not coupled in the scope probe.
3. Specified at $V_{CC,STATIC}$ (nominal) under maximum signal loading conditions.
4. Specified at the VID voltage.
5. The I_{CCDES}(max) specification comprehends future processor frequencies. Platforms should be designed to this specification.
6. Based on simulations and averaged over the duration of any change in current. Specified by design/ characterization at nominal V_{CC}. Not 100% tested.
7. Measured at the bulk capacitors on the motherboard.

Table 10. FSB Differential BCLK Specifications

Symbol	Parameter	Min	Typ	Max	Unit	Notes[1]
V_L	Input Low Voltage		0		V	
V_H	Input High Voltage	0.660	0.710	0.850	V	
V_{CROSS}	Crossing Voltage	0.25	0.35	0.55	V	2
ΔV_{CROSS}	Range of Crossing Points	N/A	N/A	0.140	V	6
V_{TH}	Threshold Region	V_{CROSS} -0.100		V_{CROSS}+0.100	V	3
I_{LI}	Input Leakage Current			± 100	µA	4
Cpad	Pad Capacitance	1.8	2.3	2.75	pF	5

NOTES:
1. Unless otherwise noted, all specifications in this table apply to all processor frequencies.
2. Crossing Voltage is defined as absolute voltage where rising edge of BCLK0 is equal to the falling edge of BCLK1.
3. Threshold Region is defined as a region entered about the crossing voltage in which the differential receiver switches. It includes input threshold hysteresis.
4. For Vin between 0 V and V_H.
5. Cpad includes die capacitance only. No package parasitics are included.

6. ΔV_{CROSS} is defined as the total variation of all crossing voltages as defined in note 2.

Table 11. AGTL+ Signal Group DC Specifications

Symbol	Parameter	Min	Typ	Max	Unit	Notes[1]
VCCP	I/O Voltage	0.997	1.05	1.102	V	
GTLREF	Reference Voltage	2/3 VCCP - 2%	2/3 VCCP	2/3 VCCP + 2%	V	6
V_{IH}	Input High Voltage	GTLREF+0.1		VCCP+0.1	V	3,4,6
V_{IL}	Input Low Voltage	-0.1		GTLREF-0.1	V	2
V_{OH}	Output High Voltage		VCCP			4,6
R_{TT}	Termination Resistance	47	55	63	W	7
R_{ON}	Buffer On Resistance	17.7	24.7	32.9	W	5
I_{LI}	Input Leakage Current			± 100	µA	8
Cpad	Pad Capacitance	1.8	2.3	2.75	pF	9

NOTES:
1. Unless otherwise noted, all specifications in this table apply to all processor frequencies.
2. V_{IL} is defined as the maximum voltage level at a receiving agent that will be interpreted as a logical low value.
3. V_{IH} is defined as the minimum voltage level at a receiving agent that will be interpreted as a logical high value.
4. V_{IH} and V_{OH} may experience excursions above VCCP. However, input signal drivers must comply with the signal quality specifications in Chapter 4.
5. This is the pull down driver resistance. Refer to processor I/O Buffer Models for I/V characteristics. Measured at 0.31 x VCCP. R_{ON} (min) = 0.38 x R_{TT}, R_{ON} (typ) = 0.45 x R_{TT}, R_{ON} (max) = 0.52 x R_{TT}.
6. GTLREF should be generated from VCCP with a 1% tolerance resistor divider. The VCCP referred to in these specifications is the instantaneous VCCP.
7. R_{TT} is the on-die termination resistance measured at V_{OL} of the AGTL+ output driver. Measured at 0.31 x VCCP. R_{TT} is connected to VCCP on die. Refer to processor I/O buffer models for I/V characteristics.
8. Specified with on die R_{TT} and R_{ON} are turned off.
9. Cpad includes die capacitance only. No package parasitics are included.

.

Table 12. CMOS Signal Group DC Specifications

Symbol	Parameter	Min	Typ	Max	Unit	Notes[1]
VCCP	I/O Voltage	0.997	1.05	1.102	V	
V_{IL}	Input Low Voltage CMOS	-0.1		0.3 x VCCP	V	2, 3
V_{IH}	Input High Voltage	0.7 x VCCP		VCCP+0.1	V	2
V_{OL}	Output Low Voltage	-0.1	0	0.1 x VCCP	V	2
V_{OH}	Output High Voltage	0.9 x VCCP	VCCP	VCCP+0.1	V	2
I_{OL}	Output Low Current	1.49		4.08	mA	4
I_{OH}	Output High Current	1.49		4.08	mA	5
I_{LI}	Leakage Current			± 100	µA	6
Cpad	Pad Capacitance	1.0	2.3	3.0	pF	7

NOTES:
1. Unless otherwise noted, all specifications in this table apply to all processor frequencies.
2. The VCCP referred to in these specifications refers to instantaneous VCCP.
3. Refer to the processor I/O Buffer Models for I/V characteristics.

4. Measured at 0.1 x VCCP.
5. Measured at 0.9 x VCCP.
6. For Vin between 0V and VCCP. Measured when the driver is tristated.
7. Cpad includes die capacitance only. No package parasitics are included.

Table 13. Open Drain Signal Group DC Specifications

Symbol	Parameter	Min	Typ	Max	Unit	Notes[1]
V_{OH}	Output High Voltage		VCCP		V	3
V_{OL}	Output Low Voltage	0		0.20	V	
I_{OL}	Output Low Current	16		50	mA	2
I_{LO}	Leakage Current			± 200	µA	4
Cpad	Pad Capacitance	1.7	2.3	3.0	pF	5

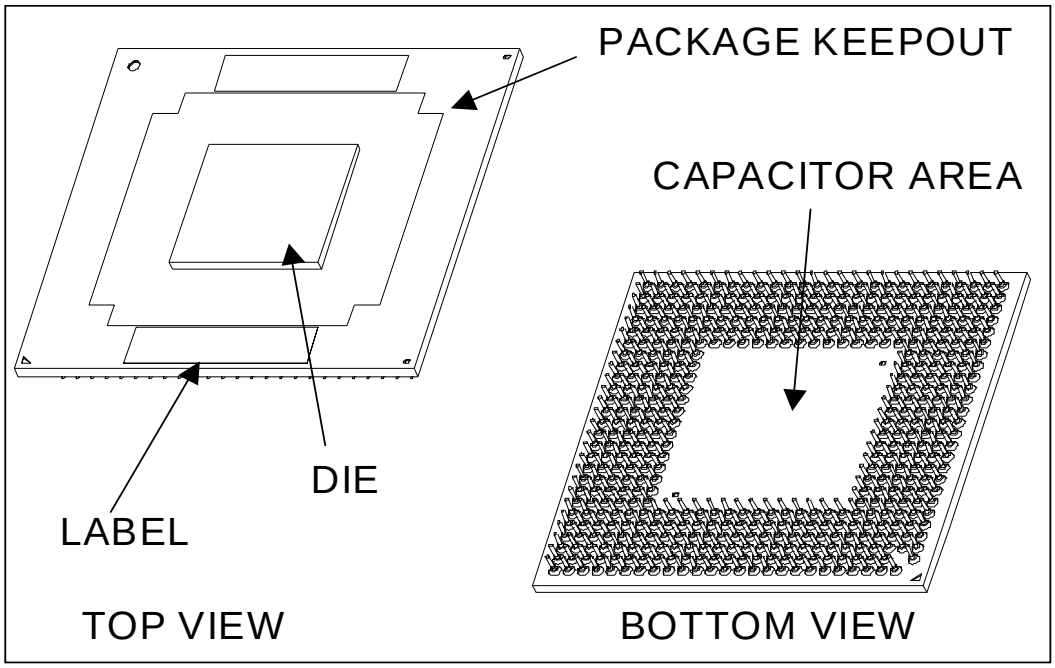
NOTES:
1. Unless otherwise noted, all specifications in this table apply to all processor frequencies.
2. Measured at 0.2 V.
3. V_{OH} is determined by value of the external pull-up resistor to VCCP. Please refer to platform RDDP for details.
4. For Vin between 0 V and V_{OH}.
5. Cpad includes die capacitance only. No package parasitics are included.

4 Package Mechanical Specifications and Pin Information

The processor is available in 478-pin Micro-FCPGA and 479 ball Micro-FCBGA packages. Different views of the Micro-FCPGA package are shown in Figure 4 through Figure 6. Package dimensions are shown in Table 14. Different views of the Micro-FCBGA package are shown in Figure 8 through Figure 10. Package dimensions are shown in Table 15. The Intel Celeron M processor die offset is illustrated in Figure 7.

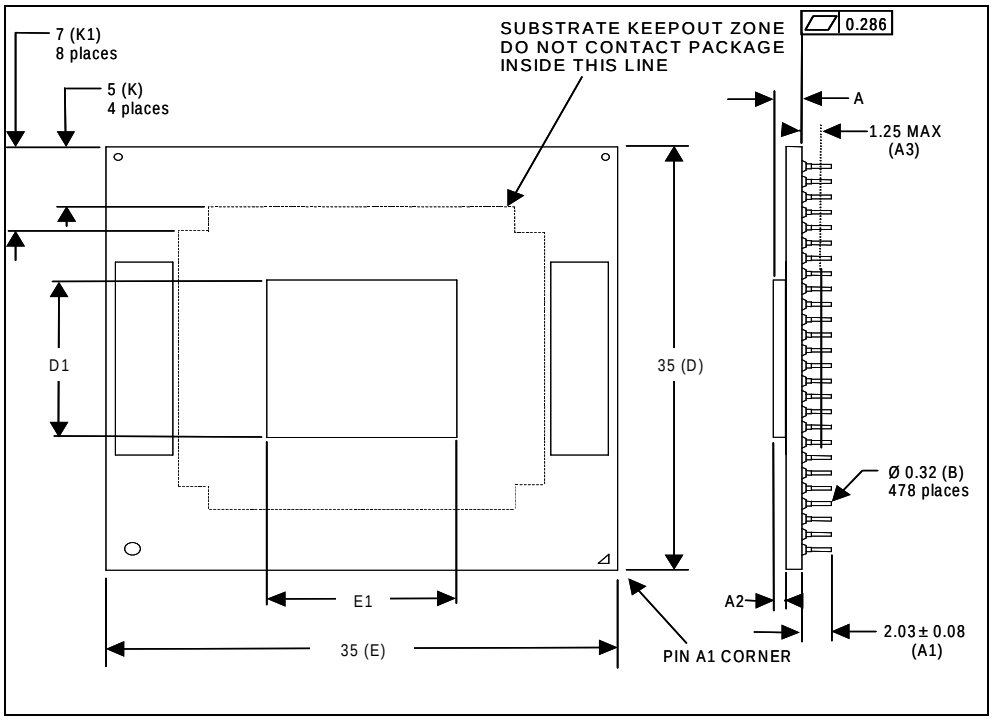
The Micro-FCBGA may have capacitors placed in the area surrounding the die. Because the die-side capacitors are electrically conductive, and only slightly shorter than the die height, care should be taken to avoid contacting the capacitors with electrically conductive materials. Doing so may short the capacitors, and possibly damage the device or render it inactive. The use of an insulating material between the capacitors and any thermal solution should be considered to prevent capacitor shorting.

Figure 4. Micro-FCPGA Package Top and Bottom Isometric Views



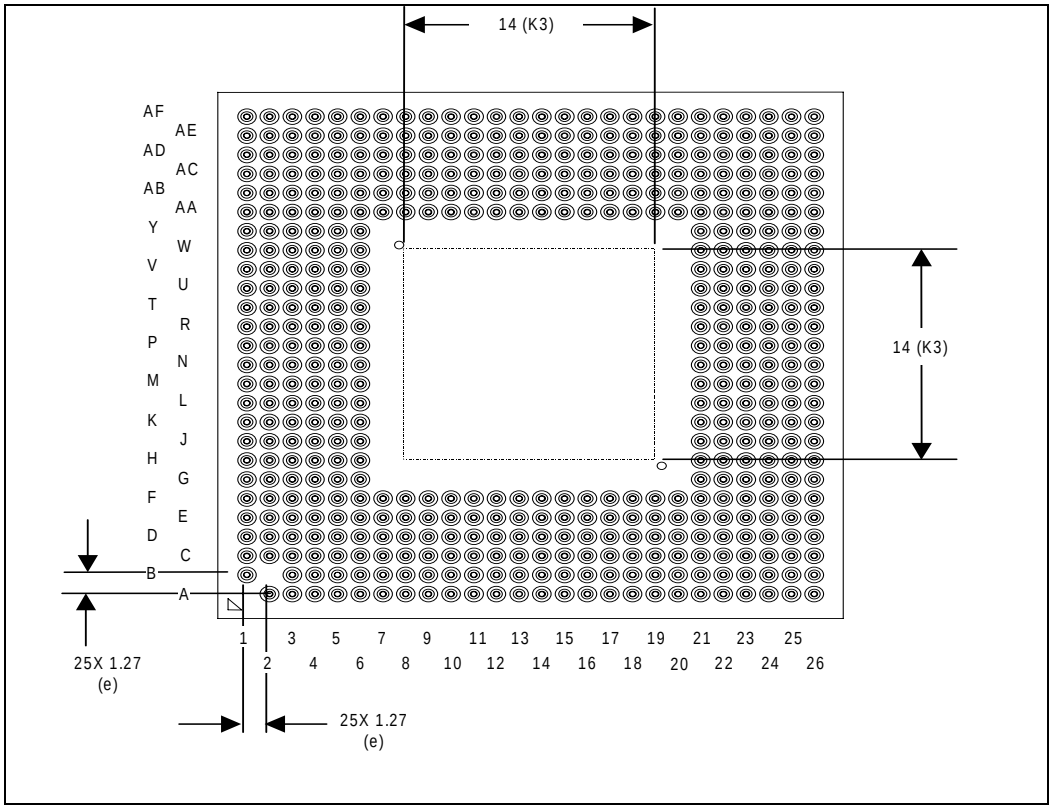
NOTE: All dimensions in millimeters. Values shown for reference only. Refer to Table 14 for details.

Figure 5. Micro-FCPGA Package - Top and Side Views



NOTE: All dimensions in millimeters. Values shown for reference only. Refer to Table 14 for details.

Figure 6. Micro-FCPGA Package - Bottom View



NOTE: All dimensions in millimeters. Values shown for reference only. Refer to Table 14 for details.

Figure 7. Intel Celeron M Processor Die Offset

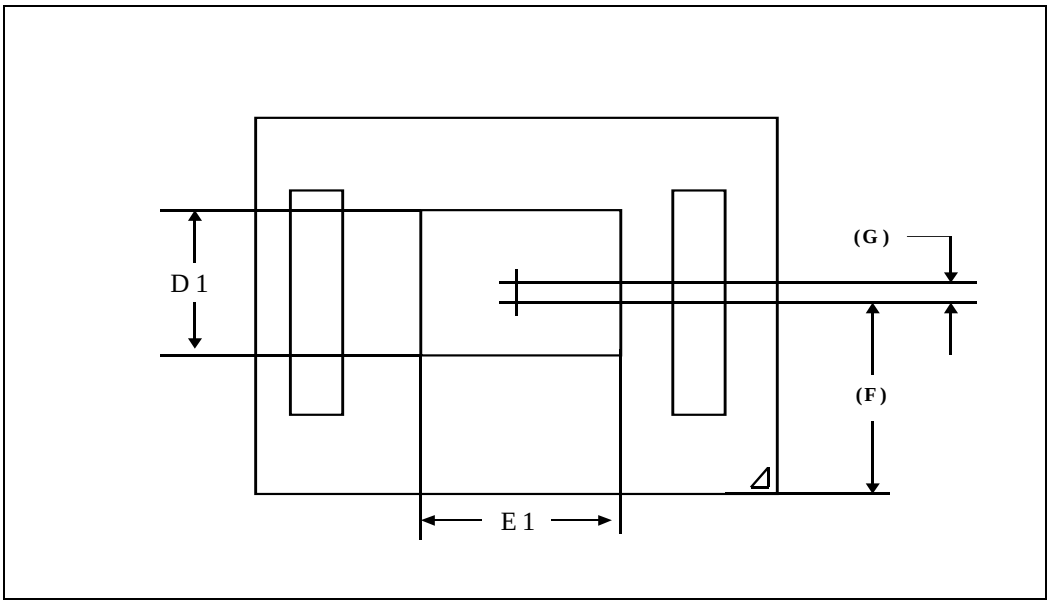


Table 14. Micro-FCPGA Package Dimensions

Symbol	Parameter	Min	Max	Unit
A	Overall height, top of die to package seating plane	1.88	2.02	mm
-	Overall height, top of die to PCB surface, including socket (Refer to Note 1)	4.74	5.16	mm
A1	Pin length	1.95	2.11	mm
A2	Die height	0.82		mm
A3	Pin-side capacitor height	-	1.25	mm
B	Pin diameter	0.28	0.36	mm
D	Package substrate length	34.9	35.1	mm
E	Package substrate width	34.9	35.1	mm
D1	Die length	10.56		mm
E1	Die width	7.84		mm
F	To Package Substrate Center	17.5		mm
G	Die Offset from Package Center	1.133		mm
e	Pin pitch	1.27		mm
K	Package edge keep-out	5		mm
K1	Package corner keep-out	7		mm
K3	Pin-side capacitor boundary	14		mm
-	Pin tip radial true position	<=0.254		mm
N	Pin count	478		each
Pdie	Allowable pressure on the die for thermal solution	-	689	kPa
W	Package weight	4.5		g
	Package Surface Flatness	0.286		mm

NOTE: Overall height with socket is based on design dimensions of the Micro-FCPGA package with no thermal solution attached. Values are based on design specifications and tolerances. This dimension is subject to change based on socket design, OEM motherboard design or OEM SMT process.

Figure 8. Micro-FCBGA Package Top and Bottom Isometric Views

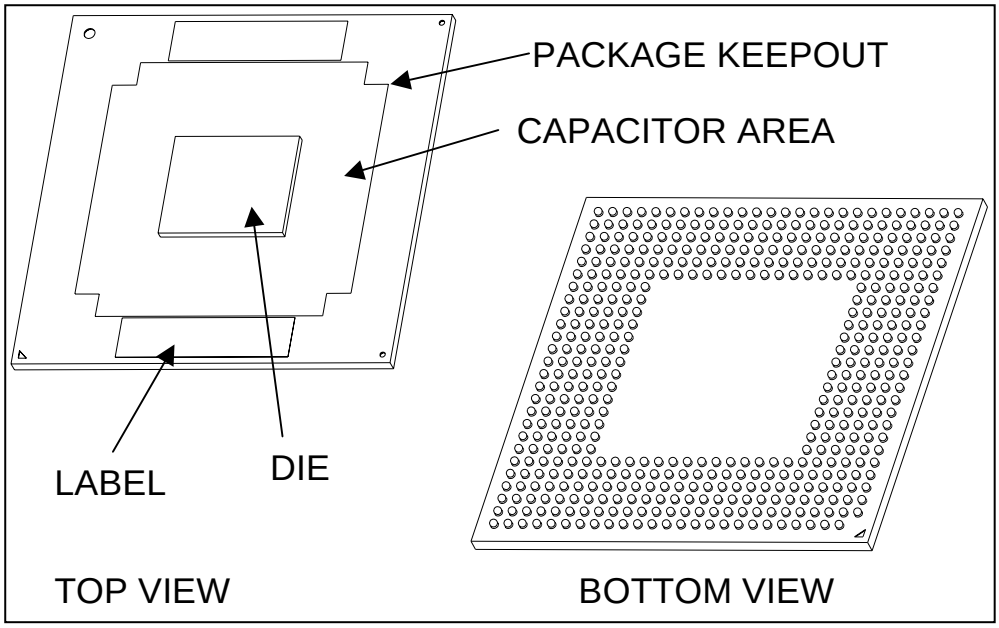

Figure 9. Micro-FCBGA Package Top and Side Views

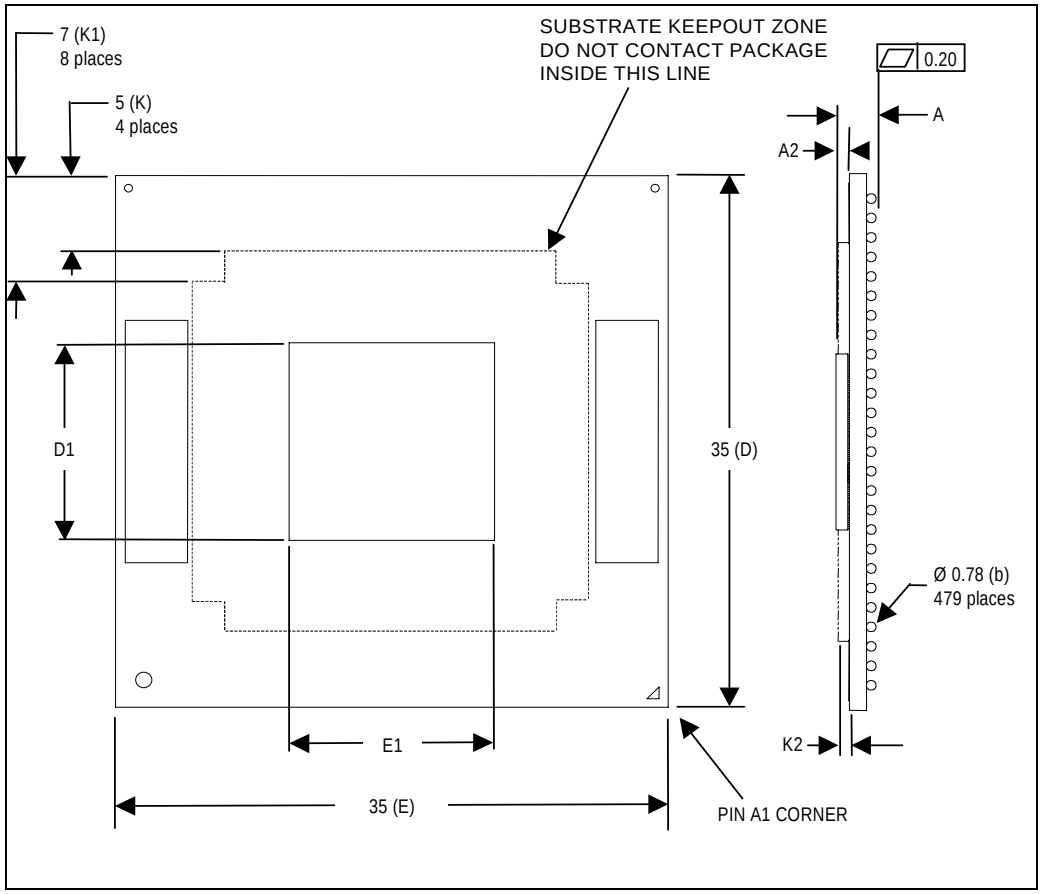
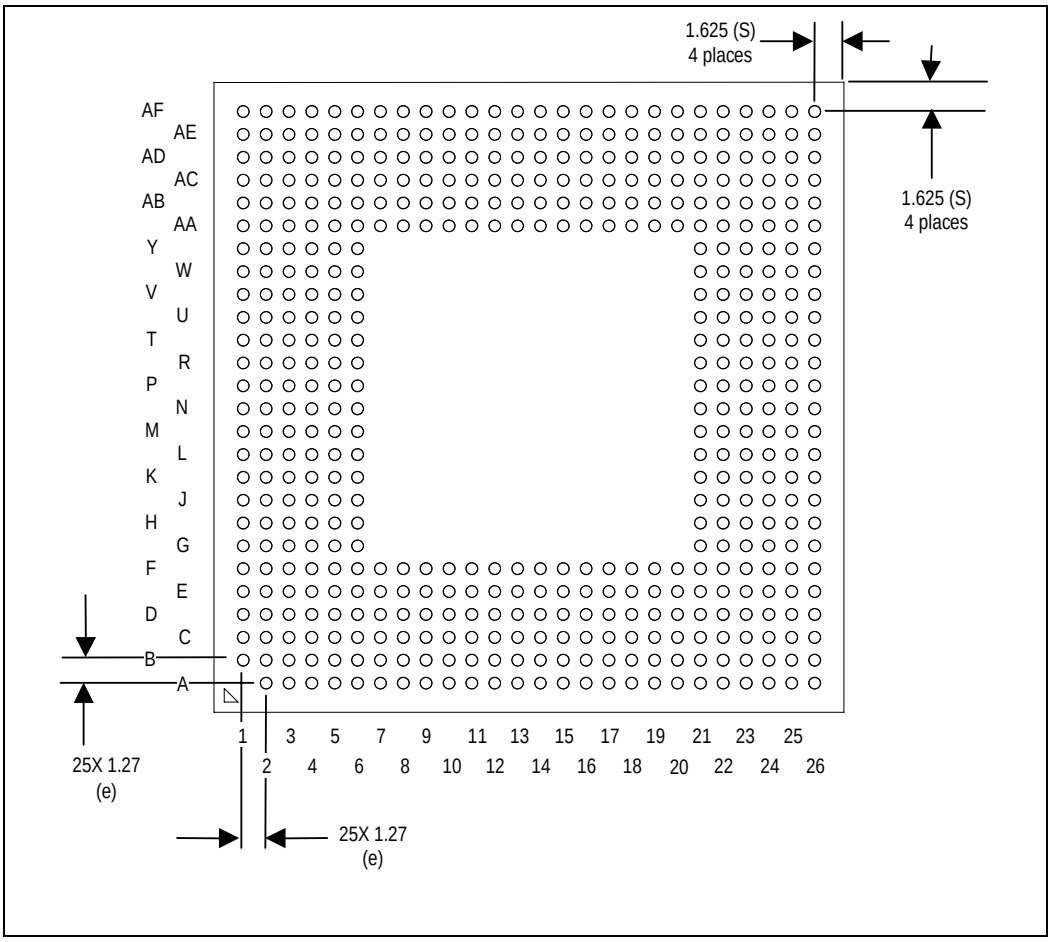


NOTE: All dimensions in millimeters. Values shown for reference only. Refer to Table 15 for details.

Figure 10. Micro-FCBGA Package Bottom View



NOTE: All dimensions in millimeters. Values shown for reference only. Refer to Table 15 for details

Table 15. Micro-FCBGA Package Dimensions

Symbol	Parameter	Min	Max	Unit
A	Overall height, as delivered (Refer to Note 1)	2.60	2.85	mm
A2	Die height	0.82		mm
b	Ball diameter	0.78		mm
D	Package substrate length	34.9	35.1	mm
E	Package substrate width	34.9	35.1	mm
D1	Die length	10.56		mm
E1	Die width	7.84		mm
F	To Package Substrate Center	17.5		mm
G	Die Offset from Package Center	1.133		mm
e	Ball pitch	1.27		mm
K	Package edge keep-out	5		mm
K1	Package corner keep-out	7		mm
K2	Die-side capacitor height	-	0.7	mm
S	Package edge to first ball center	1.625		mm
N	Ball count	479		each
-	Solder ball coplanarity	0.2		mm
Pdie	Allowable pressure on the die for thermal solution	-	689	kPa
W	Package weight	4.5		g

NOTE: Overall height as delivered. Values are based on design specifications and tolerances. This dimension is subject to change based on OEM motherboard design or OEM SMT process.

4.1 Processor Pin-Out and Pin List

Figure 11 on the next page shows the top view pinout of the Intel Celeron M processor. The pin list is arranged in two different formats, shown in Table 23 and Table 24.

4.2 Alphabetical Signals Reference

Table 25. Signal Description (Sheet 1 of 7)

Name	Type	Description
A[31:3]#	Input/ Output	A[31:3]# (Address) define a 2^{32}-byte physical memory address space. In sub-phase 1 of the address phase, these pins transmit the address of a transaction. In sub-phase 2, these pins transmit transaction type information. These signals must connect the appropriate pins of both agents on the Intel Celeron M processor FSB. A[31:3]# are source synchronous signals and are latched into the receiving buffers by ADSTB[1:0]#. Address signals are used as straps which are sampled before RESET# is deasserted.
A20M#	Input	If A20M# (Address-20 Mask) is asserted, the processor masks physical address bit 20 (A20#) before looking up a line in any internal cache and before driving a read/write transaction on the bus. Asserting A20M# emulates the 8086 processor's address wrap-around at the 1-MB boundary. Assertion of A20M# is only supported in real mode. A20M# is an asynchronous signal. However, to ensure recognition of this signal following an Input/Output write instruction, it must be valid along with the TRDY# assertion of the corresponding Input/Output Write bus transaction.
ADS#	Input/ Output	ADS# (Address Strobe) is asserted to indicate the validity of the transaction address on the A[31:3]# and REQ[4:0]# pins. All bus agents observe the ADS# activation to begin parity checking, protocol checking, address decode, internal snoop, or deferred reply ID match operations associated with the new transaction.
ADSTB[1:0]#	Input/ Output	Address strobes are used to latch A[31:3]# and REQ[4:0]# on their rising and falling edges. Strobes are associated with signals as shown below. **Signals** / **Associated Strobe** REQ[4:0]#, A[16:3]# / ADSTB[0]# A[31:17]# / ADSTB[1]#
BCLK[1:0]	Input	The differential pair BCLK (Bus Clock) determines the FSB frequency. All FSB agents must receive these signals to drive their outputs and latch their inputs. All external timing parameters are specified with respect to the rising edge of BCLK0 crossing V_{CROSS}.
BNR#	Input/ Output	BNR# (Block Next Request) is used to assert a bus stall by any bus agent who is unable to accept new bus transactions. During a bus stall, the current bus owner cannot issue any new transactions.
BPM[2:0]# BPM[3]	Output Input/ Output	BPM[3:0]# (Breakpoint Monitor) are breakpoint and performance monitor signals. They are outputs from the processor which indicate the status of breakpoints and programmable counters used for monitoring processor performance. BPM[3:0]# should connect the appropriate pins of all Intel Celeron M processor FSB agents.This includes debug or performance monitoring tools. Please refer to the platform design guides and *ITP700 Debug Port Design Guide* for more detailed information.
BPRI#	Input	BPRI# (Bus Priority Request) is used to arbitrate for ownership of the FSB. It must connect the appropriate pins of both FSB agents. Observing BPRI# active (as asserted by the priority agent) causes the other agent to stop issuing new requests, unless such requests are part of an ongoing locked operation. The priority agent keeps BPRI# asserted until all of its requests are completed, then releases the bus by deasserting BPRI#.
BR0#	Input/ Output	BR0# is used by the processor to request the bus. The arbitration is done between the Intel Celeron M processor (Symmetric Agent) and MCH-M (High Priority Agent) of the Intel 852GM, Intel 855PM, and Intel 855GM chipsets.

Table 25. Signal Description (Sheet 2 of 7)

<table>
<tr><th>Name</th><th>Type</th><th>Description</th></tr>
<tr><td>COMP[3:0]</td><td>Analog</td><td>COMP[3:0] must be terminated on the system board using precision (1% tolerance) resistors. Refer to the platform design guides for more details on implementation.</td></tr>
<tr><td>D[63:0]#</td><td>Input/ Output</td><td>D[63:0]# (Data) are the data signals. These signals provide a 64-bit data path between the FSB agents, and must connect the appropriate pins on both agents. The data driver asserts DRDY# to indicate a valid data transfer.
D[63:0]# are quad-pumped signals and will thus be driven four times in a common clock period. D[63:0]# are latched off the falling edge of both DSTBP[3:0]# and DSTBN[3:0]#. Each group of 16 data signals correspond to a pair of one DSTBP# and one DSTBN#. The following table shows the grouping of data signals to data strobes and DINV#.
Quad-Pumped Signal Groups
<table>
<tr><th>Data Group</th><th>DSTBN#/ DSTBP#</th><th>DINV#</th></tr>
<tr><td>D[15:0]#</td><td>0</td><td>0</td></tr>
<tr><td>D[31:16]#</td><td>1</td><td>1</td></tr>
<tr><td>D[47:32]#</td><td>2</td><td>2</td></tr>
<tr><td>D[63:48]#</td><td>3</td><td>3</td></tr>
</table>
Furthermore, the DINV# pins determine the polarity of the data signals. Each group of 16 data signals corresponds to one DINV# signal. When the DINV# signal is active, the corresponding data group is inverted and therefore sampled active high.</td></tr>
<tr><td>DBR#</td><td>Output</td><td>DBR# (Data Bus Reset) is used only in processor systems where no debug port is implemented on the system board. DBR# is used by a debug port interposer so that an in-target probe can drive system reset. If a debug port is implemented in the system, DBR# is a no connect. DBR# is not a processor signal.</td></tr>
<tr><td>DBSY#</td><td>Input/ Output</td><td>DBSY# (Data Bus Busy) is asserted by the agent responsible for driving data on the FSB to indicate that the data bus is in use. The data bus is released after DBSY# is deasserted. This signal must connect the appropriate pins on both FSB agents.</td></tr>
<tr><td>DEFER#</td><td>Input</td><td>DEFER# is asserted by an agent to indicate that a transaction cannot be guaranteed in-order completion. Assertion of DEFER# is normally the responsibility of the addressed memory or Input/Output agent. This signal must connect the appropriate pins of both FSB agents.</td></tr>
<tr><td>DINV[3:0]#</td><td>Input/ Output</td><td>DINV[3:0]# (Data Bus Inversion) are source synchronous and indicate the polarity of the D[63:0]# signals. The DINV[3:0]# signals are activated when the data on the data bus is inverted. The bus agent will invert the data bus signals if more than half the bits, within the covered group, would change level in the next cycle.
DINV[3:0]# Assignment To Data Bus
<table>
<tr><th>Bus Signal</th><th>Data Bus Signals</th></tr>
<tr><td>DINV[3]#</td><td>D[63:48]#</td></tr>
<tr><td>DINV[2]#</td><td>D[47:32]#</td></tr>
<tr><td>DINV[1]#</td><td>D[31:16]#</td></tr>
<tr><td>DINV[0]#</td><td>D[15:0]#</td></tr>
</table></td></tr>
</table>

Table 25. Signal Description (Sheet 3 of 7)

<table>
<tr><th>Name</th><th>Type</th><th>Description</th></tr>
<tr><td>DPSLP#</td><td>Input</td><td>DPSLP# when asserted on the platform causes the processor to transition from the Sleep State to the Deep Sleep state. In order to return to the Sleep State, DPSLP# must be deasserted. DPSLP# is driven by the ICH4-M component and also connects to the MCH-M component of the Intel 855PM, Intel 855GM, or 852GM chipset.</td></tr>
<tr><td>DPWR#</td><td>Input</td><td>DPWR# is a control signal from the Intel 855PM and Intel 855GM chipsets used to reduce power on the Intel Celeron M processor data bus input buffers.</td></tr>
<tr><td>DRDY#</td><td>Input/ Output</td><td>DRDY# (Data Ready) is asserted by the data driver on each data transfer, indicating valid data on the data bus. In a multi-common clock data transfer, DRDY# may be deasserted to insert idle clocks. This signal must connect the appropriate pins of both FSB agents.</td></tr>
<tr><td>DSTBN[3:0]#</td><td>Input/ Output</td><td>Data strobe used to latch in D[63:0]#.
<table>
<tr><th>Signals</th><th>Associated Strobe</th></tr>
<tr><td>D[15:0]#, DINV[0]#</td><td>DSTBN[0]#</td></tr>

<tr><td>D[47:32]#, DINV[2]#</td><td>DSTBN[2]#</td></tr>
<tr><td>D[63:48]#, DINV[3]#</td><td>DSTBN[3]#</td></tr>
</table></td></tr>
<tr><td>DSTBP[3:0]#</td><td>Input/ Output</td><td>Data strobe used to latch in D[63:0]#.
<table>
<tr><th>Signals</th><th>Associated Strobe</th></tr>
<tr><td>D[15:0]#, DINV[0]#</td><td>DSTBP[0]#</td></tr>
<tr><td>D[31:16]#, DINV[1]#</td><td>DSTBP[1]#</td></tr>
<tr><td>D[47:32]#, DINV[2]#</td><td>DSTBP[2]#</td></tr>
<tr><td>D[63:48]#, DINV[3]#</td><td>DSTBP[3]#</td></tr>
</table></td></tr>
<tr><td>FERR#/PBE#</td><td>Output</td><td>FERR# (Floating-point Error)/PBE#(Pending Break Event) is a multiplexed signal and its meaning is qualified with STPCLK#. When STPCLK# is not asserted, FERR#/PBE# indicates a floating point when the processor detects an unmasked floating-point error. FERR# is similar to the ERROR# signal on the Intel 387 coprocessor, and is included for compatibility with systems using MS-DOS*-type floating-point error reporting. When STPCLK# is asserted, an assertion of FERR#/PBE# indicates that the processor has a pending break event waiting for service. The assertion of FERR#/PBE# indicates that the processor should be returned to the Normal state. When FERR#/PBE# is asserted, indicating a break event, it will remain asserted until STPCLK# is deasserted. Assertion of PREQ# when STPCLK# is active will also cause an FERR# break event. For additional information on the pending break event functionality, including identification of support of the feature and enable/disable information, refer to Volume 3 of the Intel® Architecture Software Developer's Manual and the Intel® Processor Identification and CPUID Instruction application note.
For termination requirements please refer to the platform design guides.</td></tr>
<tr><td>GTLREF</td><td>Input</td><td>GTLREF determines the signal reference level for AGTL+ input pins. GTLREF should be set at 2/3 V_{CCP}. GTLREF is used by the AGTL+ receivers to determine if a signal is a logical 0 or logical 1. Please refer to the platform design guides for details on GTLREF implementation.</td></tr>
</table>

Table 25. Signal Description (Sheet 4 of 7)

Name	Type	Description
HIT# HITM#	Input/ Output Input/ Output	HIT# (Snoop Hit) and HITM# (Hit Modified) convey transaction snoop operation results. Either FSB agent may assert both HIT# and HITM# together to indicate that it requires a snoop stall, which can be continued by reasserting HIT# and HITM# together.
IERR#	Output	IERR# (Internal Error) is asserted by a processor as the result of an internal error. Assertion of IERR# is usually accompanied by a SHUTDOWN transaction on the FSB. This transaction may optionally be converted to an external error signal (e.g., NMI) by system core logic. The processor will keep IERR# asserted until the assertion of RESET#, BINIT#, or INIT#. For termination requirements please refer to the platform design guides.
IGNNE#	Input	IGNNE# (Ignore Numeric Error) is asserted to force the processor to ignore a numeric error and continue to execute noncontrol floating-point instructions. If IGNNE# is deasserted, the processor generates an exception on a noncontrol floating-point instruction if a previous floating-point instruction caused an error. IGNNE# has no effect when the NE bit in control register 0 (CR0) is set. IGNNE# is an asynchronous signal. However, to ensure recognition of this signal following an Input/Output write instruction, it must be valid along with the TRDY# assertion of the corresponding Input/Output Write bus transaction.
INIT#	Input	INIT# (Initialization), when asserted, resets integer registers inside the processor without affecting its internal caches or floating-point registers. The processor then begins execution at the power-on Reset vector configured during power-on configuration. The processor continues to handle snoop requests during INIT# assertion. INIT# is an asynchronous signal. However, to ensure recognition of this signal following an Input/Output Write instruction, it must be valid along with the TRDY# assertion of the corresponding Input/Output Write bus transaction. INIT# must connect the appropriate pins of both FSB agents. If INIT# is sampled active on the active to inactive transition of RESET#, then the processor executes its Built-in Self-Test (BIST). For termination requirements please refer to the platform design guides.
ITP_CLK[1:0]	Input	ITP_CLK[1:0] are copies of BCLK that are used only in processor systems where no debug port is implemented on the system board. ITP_CLK[1:0] are used as BCLK[1:0] references for a debug port implemented on an interposer. If a debug port is implemented in the system, ITP_CLK[1:0] are no connects. These are not processor signals.
LINT[1:0]	Input	LINT[1:0] (Local APIC Interrupt) must connect the appropriate pins of all APIC Bus agents. When the APIC is disabled, the LINT0 signal becomes INTR, a maskable interrupt request signal, and LINT1 becomes NMI, a nonmaskable interrupt. INTR and NMI are backward compatible with the signals of those names on the Pentium® processor. Both signals are asynchronous. Both of these signals must be software configured via BIOS programming of the APIC register space to be used either as NMI/INTR or LINT[1:0]. Because the APIC is enabled by default after Reset, operation of these pins as LINT[1:0] is the default configuration.
LOCK#	Input/ Output	LOCK# indicates to the system that a transaction must occur atomically. This signal must connect the appropriate pins of both FSB agents. For a locked sequence of transactions, LOCK# is asserted from the beginning of the first transaction to the end of the last transaction. When the priority agent asserts BPRI# to arbitrate for ownership of the FSB, it will wait until it observes LOCK# deasserted. This enables symmetric agents to retain ownership of the FSB throughout the bus locked operation and ensure the atomicity of lock.

Table 25. Signal Description (Sheet 5 of 7)

Name	Type	Description
PRDY#	Output	Probe Ready signal used by debug tools to determine processor debug readiness. Please refer to the *ITP700 Debug Port Design Guide* and the platform design guides for more implementation details.
PREQ#	Input	Probe Request signal used by debug tools to request debug operation of the processor. Please refer to the *ITP700 Debug Port Design Guide* and the platform design guides for more implementation details.
PROCHOT#	Output	PROCHOT# (Processor Hot) will go active when the processor temperature monitoring sensor detects that the processor has reached its maximum safe operating temperature. This indicates that the processor Thermal Control Circuit has been activated, if enabled. See Chapter 5 for more details. For termination requirements please refer to the platform design guides. This signal may require voltage translation on the motherboard. Please refer to the platform design guides for more details.
PSI#	Output	Processor Power Status Indicator signal. This signal is asserted when the processor is in a lower state (Deep Sleep). See Section 2.1.4 for more details. Please refer to the *IMVP-IV Mobile Processor and Mobile Chipset Voltage Regulation with Power Status Indicator (PSI) Specification* for more details on the PSI# signal.
PWRGOOD	Input	PWRGOOD (Power Good) is a processor input. The processor requires this signal to be a clean indication that the clocks and power supplies are stable and within their specifications. 'Clean' implies that the signal will remain low (capable of sinking leakage current), without glitches, from the time that the power supplies are turned on until they come within specification. The signal must then transition monotonically to a high state. PWRGOOD can be driven inactive at any time, but clocks and power must again be stable before a subsequent rising edge of PWRGOOD. The PWRGOOD signal must be supplied to the processor; it is used to protect internal circuits against voltage sequencing issues. It should be driven high throughout boundary scan operation. For termination requirements please refer to the platform design guides.
REQ[4:0]#	Input/ Output	REQ[4:0]# (Request Command) must connect the appropriate pins of both FSB agents. They are asserted by the current bus owner to define the currently active transaction type. These signals are source synchronous to ADSTB[0]#.
RESET#	Input	Asserting the RESET# signal resets the processor to a known state and invalidates its internal caches without writing back any of their contents. For a power-on Reset, RESET# must stay active for at least two milliseconds after V_{CC} and BCLK have reached their proper specifications. On observing active RESET#, both FSB agents will deassert their outputs within two clocks. All processor straps must be valid within the specified setup time before RESET# is deasserted. Please refer to the *ITP700 Debug Port Design Guide* and the platform design guides for termination requirements and implementation details. There is a 55 ohm (nominal) on die pull-up resistor on this signal.
RS[2:0]#	Input	RS[2:0]# (Response Status) are driven by the response agent (the agent responsible for completion of the current transaction), and must connect the appropriate pins of both FSB agents.
RSVD	Reserved/ No Connect	These pins are RESERVED and must be left unconnected on the board. However, it is recommended that routing channels to these pins on the board be kept open for possible future use. Please refer to the platform design guides for more details.

Table 25. Signal Description (Sheet 6 of 7)

Name	Type	Description
SLP#	Input	SLP# (Sleep), when asserted in Stop-Grant state, causes the processor to enter the Sleep state. During Sleep state, the processor stops providing internal clock signals to all units, leaving only the Phase-Locked Loop (PLL) still operating. Processors in this state will not recognize snoops or interrupts. The processor will recognize only assertion of the RESET# signal, deassertion of SLP#, and removal of the BCLK input while in Sleep state. If SLP# is deasserted, the processor exits Sleep state and returns to Stop-Grant state, restarting its internal clock signals to the bus and processor core units. If DPSLP# is asserted while in the Sleep state, the processor will exit the Sleep state and transition to the Deep Sleep state.
SMI#	Input	SMI# (System Management Interrupt) is asserted asynchronously by system logic. On accepting a System Management Interrupt, the processor saves the current state and enter System Management Mode (SMM). An SMI Acknowledge transaction is issued, and the processor begins program execution from the SMM handler. If SMI# is asserted during the deassertion of RESET# the processor will tristate its outputs.
STPCLK#	Input	STPCLK# (Stop Clock), when asserted, causes the processor to enter a low power Stop-Grant state. The processor issues a Stop-Grant Acknowledge transaction, and stops providing internal clock signals to all processor core units except the FSB and APIC units. The processor continues to snoop bus transactions and service interrupts while in Stop-Grant state. When STPCLK# is deasserted, the processor restarts its internal clock to all units and resumes execution. The assertion of STPCLK# has no effect on the bus clock; STPCLK# is an asynchronous input.
TCK	Input	TCK (Test Clock) provides the clock input for the processor Test Bus (also known as the Test Access Port). Please refer to the *ITP700 Debug Port Design Guide* and the platform design guides for termination requirements and implementation details.
TDI	Input	TDI (Test Data In) transfers serial test data into the processor. TDI provides the serial input needed for JTAG specification support. Please refer to the *ITP700 Debug Port Design Guide* and the platform design guides for termination requirements and implementation details.
TDO	Output	TDO (Test Data Out) transfers serial test data out of the processor. TDO provides the serial output needed for JTAG* specification support. Please refer to the *ITP700 Debug Port Design Guide* and the platform design guides for termination requirements and implementation details.
TEST1, TEST2, TEST3	Input	TEST1, TEST2, and TEST3 must be left unconnected but should have a stuffing option connection to V_{SS} separately using 1-k, pull-down resistors. Please refer to the platform design guides for more details.
THERMDA	Other	Thermal Diode Anode.
THERMDC	Other	Thermal Diode Cathode.
THERMTRIP#	Output	The processor protects itself from catastrophic overheating by use of an internal thermal sensor. This sensor is set well above the normal operating temperature to ensure that there are no false trips. The processor will stop all execution when the junction temperature exceeds approximately 125°C. This is signalled to the system by the THERMTRIP# (Thermal Trip) pin. For termination requirements please refer to the platform design guides.
TMS	Input	TMS (Test Mode Select) is a JTAG specification support signal used by debug tools. Please refer to the *ITP700 Debug Port Design Guide* and the platform design guides for termination requirements and implementation details.

Table 25. Signal Description (Sheet 7 of 7)

Name	Type	Description
TRDY#	Input	TRDY# (Target Ready) is asserted by the target to indicate that it is ready to receive a write or implicit writeback data transfer. TRDY# must connect the appropriate pins of both FSB agents.
TRST#	Input	TRST# (Test Reset) resets the Test Access Port (TAP) logic. TRST# must be driven low during power on Reset. Please refer to the *ITP700 Debug Port Design Guide* and the platform design guides for termination requirements and implementation details.
V_{CC}	Input	Processor core power supply.
V_{CCA}[3:0]	Input	V_{CCA} provides isolated power for the internal processor core PLLs. Refer to the platform design guides for complete implementation details.
V_{CCP}	Input	Processor I/O power supply.
V_{CCQ}[1:0]	Input	Quiet power supply for on die COMP circuitry. These pins should be connected to V_{CCP} on the motherboard. However, these connections should enable addition of decoupling on the V_{CCQ} lines if necessary.
$V_{CCSENSE}$	Output	$V_{CCSENSE}$ is an isolated low impedance connection to processor core power (V_{CC}). It can be used to sense or measure power near the silicon with little noise. Please refer to the platform design guides for termination recommendations and more details.
VID[5:0]	Output	VID[5:0] (Voltage ID) pins are used to support automatic selection of power supply voltages (Vcc). Unlike some previous generations of processors, these are CMOS signals that are driven by the Intel Celeron M processor. The voltage supply for these pins must be valid before the VR can supply Vcc to the processor. Conversely, the VR output must be disabled until the voltage supply for the VID pins becomes valid. The VID pins are needed to support the processor voltage specification variations. See Table 2 for the encoding of these pins. The VR must supply the voltage that is requested by the pins, or disable itself.
$V_{SSSENSE}$	Output	$V_{SSSENSE}$ is an isolated low impedance connection to processor core V_{SS}. It can be used to sense or measure ground near the silicon with little noise. Please refer to the platform design guides for termination recommendations and more details.

5 Thermal Specifications and Design Considerations

The Intel Celeron M processor requires a thermal solution to maintain temperatures within operating limits. A complete thermal solution includes both component and system level thermal management features. Component level thermal solutions include active or passive heatsinks or heat exchangers attached to the processor exposed die. The solution should make firm contact with the die while maintaining processor mechanical specifications such as pressure. A typical system level thermal solution may consist of a processor fan ducted to a heat exchanger that is thermally coupled to the processor using a heat pipe or direct die attachment. A secondary fan or air from the processor fan may also be used to cool other platform components or lower the internal ambient temperature within the system. The processor must remain within the minimum and maximum junction temperature (Tj) specifications at the corresponding thermal design power (TDP) value listed in Table 26. The maximum junction temperature is defined by an activation of the Intel Thermal Monitor in the processor.

Refer to Section 5.1.2 for more details. Analysis indicates that real applications are unlikely to cause the processor to consume the theoretical maximum power dissipation for sustained time periods. Intel recommends that complete thermal solution designs target the TDP indicated in Table 26. The Intel® Thermal Monitor feature is designed to help protect the processor in the unlikely event that an application exceeds the TDP recommendation for a sustained period of time. For more details on the usage of this feature, refer to Section 5.1.2. In all cases the Intel Thermal Monitor feature must be enabled for the processor to remain within specification.

Table 26. Power Specifications for the Intel Celeron M Processor

Symbol	Core Frequency & Voltage	Thermal Design Power			Unit	Notes
TDP	1.20 GHz & 1.356 V 1.30 GHz & 1.356 V 800 MHz and 1.004 V (ULV Intel Celeron M processor)	24.5 24.5 7			W	At 100 °C, Notes 1, 4
Symbol	**Parameter**	**Min**	**Typ**	**Max**	**Unit**	**Notes**
P_{AH}, P_{SGNT}	Auto Halt, Stop Grant Power at: 1.356 V (1.20 GHz) 1.356 V (1.30 GHz) 1.004 V (800 MHz ULV)			9.9 9.5 2.0	W	At 50 °C, Note 2
P_{SLP}	Sleep Power at: 1.356 V (1.20 GHz) 1.356 V (1.30 GHz) 1.004 V (800 MHz ULV)			9.7 9.3 1.9	W	At 50 °C, Note 2
P_{DSLP}	Deep Sleep Power at: 1.356 V (1.20 GHz) 1.356 V (1.30 GHz) 1.004 V (800 MHz ULV)			7.7 7.3 1.5	W	At 35 °C, Note 2
T_J	Junction Temperature	0		100	°C	Notes 3, 4

NOTES:
1. The TDP specification should be used to design the processor thermal solution. The TDP is not the maximum theoretical power the processor can dissipate.
2. Not 100% tested. These power specifications are determined by characterization of the processor currents at higher temperatures and extrapolating the values for the temperature indicated.
3. As measured by the on-die Intel Thermal Monitor. The Intel Thermal Monitor's automatic mode is used to indicate that the maximum T_J has been reached. Refer to Section 5.1 for more details.
4. The Intel Thermal Monitor automatic mode must be enabled for the processor to operate within specifications.

5.1 Thermal Specifications

5.1.1 Thermal Diode

The Intel Celeron M processor incorporates two methods of monitoring die temperature, the Intel Thermal Monitor and the thermal diode. The Intel Thermal Monitor (detailed in Section 5.1) must be used to determine when the maximum specified processor junction temperature has been reached. The second method, the thermal diode, can be read by an off-die analog/digital converter (a thermal sensor) located on the motherboard, or a standalone measurement kit. The thermal diode may be used to monitor the die temperature of the processor for thermal management or instrumentation purposes but cannot be used to indicate that the maximum T_J of the processor has been reached. Please see Section 5.1.2 for thermal diode usage recommendation when the PROCHOT# signal is not asserted.

Table 27 and Table 28 provide the diode interface and specifications.

Note: The reading of the external thermal sensor (on the motherboard) connected to the processor thermal diode signals, will not necessarily reflect the temperature of the hottest location on the die. This is due to inaccuracies in the external thermal sensor, on-die temperature gradients between the location of the thermal diode and the hottest location on the die, and time based variations in the die temperature measurement. Time based variations can occur when the sampling rate of the thermal diode (by the thermal sensor) is slower than the rate at which the T_J temperature can change.

The offset between the thermal diode based temperature reading and the Intel Thermal Monitor reading may be characterized using the Intel Thermal Monitor's automatic mode activation of thermal control circuit. This temperature offset must be taken into account when using the processor thermal diode to implement power management events.

Table 27. Thermal Diode Interface

Signal Name	Pin/Ball Number	Signal Description
THERMDA	B18	Thermal diode anode
THERMDC	A18	Thermal diode cathode

Table 28. Thermal Diode Specifications

Symbol	Parameter	Min	Typ	Max	Unit	Notes
I_{FW}	Forward Bias Current	5		300	µA	1
n	Diode Ideality Factor	1.00151	1.00220	1.00289		2, 3, 4
R_T	Series Resistance		3.06		ohms	2, 3, 5

NOTES:
1. Intel does not support or recommend operation of the thermal diode under reverse bias. Intel does not support or recommend operation of the thermal diode when the processor power supplies are not within their specified tolerance range.
2. Characterized at 100 °C.
3. Not 100% tested. Specified by design/characterization.
4. The ideality factor, n, represents the deviation from ideal diode behavior as exemplified by the diode equation:
   $I_{FW}=I_s \times (e^{(qV_D/nkT)} -1)$
   Where I_S = saturation current, q = electronic charge, V_D = voltage across the diode, k = Boltzmann Constant, and T = absolute temperature (Kelvin).
5. The series resistance, R_T, is provided to allow for a more accurate measurement of the diode junction temperature. R_T as defined includes the pins of the processor but does not include any socket resistance or board trace resistance between the socket and the external remote diode thermal sensor. R_T can be used by remote diode thermal sensors with automatic series resistance cancellation to calibrate out this error term. Another application is that a temperature offset can be manually calculated and programmed into an offset register in the remote diode thermal sensors as exemplified by the equation:
   $T_{error} = [R_T \times (N-1) \times I_{FWmin}]/[(no/q) \times \ln N]$

5.1.2 Intel Thermal Monitor

The Intel Thermal Monitor helps control the processor temperature by activating the TCC when the processor silicon reaches its maximum operating temperature. The temperature at which the Intel Thermal Monitor activates the thermal control circuit (TCC) is not user configurable and is not software visible. Bus traffic is snooped in the normal manner, and interrupt requests are latched (and serviced during the time that the clocks are on) while the TCC is active.

With a properly designed and characterized thermal solution, it is anticipated that the TCC would only be activated for very short periods of time when running the most power intensive applications. The processor performance impact due to these brief periods of TCC activation is expected to be so minor that it would not be detectable. An under-designed thermal solution that is not able to prevent excessive activation of the TCC in the anticipated ambient environment may cause a noticeable performance loss, and may affect the long-term reliability of the processor. In addition, a thermal solution that is significantly underdesigned may not be capable of cooling the processor even when the TCC is active continuously.

The Intel Thermal Monitor controls the processor temperature by modulating (starting and stopping) the processor core clocks when the processor silicon reaches its maximum operating temperature. The Intel Thermal Monitor uses two modes to activate the TCC: Automatic mode and On-Demand mode. If both modes are activated, automatic mode takes precedence. The Intel Thermal Monitor Automatic Mode must be enabled via BIOS for the processor to be operating within specifications.This mode is selected by writing values to the Model Specific Registers (MSRs) of the processor. After the automatic mode is enabled, the TCC will activate only when the internal die temperature reaches the maximum allowed value for operation.

When Intel Thermal Monitor is enabled, and a high temperature situation exists, the clocks will be modulated by alternately turning the clocks off and on at a 50% duty cycle. Cycle times are processor speed dependent and will decrease linearly as processor core frequencies increase. After the temperature has returned to a non-critical level, modulation ceases and the TCC goes inactive. A small amount of hysteresis has been included to prevent rapid active/inactive transitions of the TCC when the processor temperature is near the trip point. The duty cycle is factory configured and cannot be modified. Also, the automatic mode does not require any additional hardware, software drivers or interrupt handling routines. Processor performance will be decreased by the same amount as the duty cycle when the TCC is active, however, with a properly designed and characterized thermal solution the TCC most likely will never be activated, or will be activated only briefly during the most power intensive applications.

The TCC may also be activated using On-Demand mode. If bit 4 of the ACPI Intel Thermal Monitor Control register is written to a "1", the TCC will be activated immediately, independent of the processor temperature. When using On-Demand mode to activate the TCC, the duty cycle of the clock modulation is programmable via bits 3:1 of the same ACPI Intel Thermal Monitor Control Register. In automatic mode, the duty cycle is fixed at 50% on, 50% off, in On-Demand mode, the duty cycle can be programmed from 12.5% on/ 87.5% off, to 87.5% on/12.5% off in 12.5% increments. On-Demand mode can be used at the same time automatic mode is enabled, however, if the system tries to enable the TCC via On-Demand mode at the same time automatic mode is enabled and a high temperature condition exists, automatic mode will take precedence.

An external signal, PROCHOT# (processor hot) is asserted when the processor detects that its temperature is above the thermal trip point. Bus snooping and interrupt latching are also active while the TCC is active.

Note: PROCHOT# will not be asserted when the processor is in the Stop-Grant, Sleep, and Deep Sleep low power states (internal clocks stopped), hence the thermal diode reading must be used as a

safeguard to maintain the processor junction temperature within the 100 °C (maximum) specification. If the platform thermal solution is not able to maintain the processor junction temperature within the maximum specification, the system must initiate an orderly shutdown to prevent damage. If the processor enters one of the above low power states with PROCHOT# already asserted, PROCHOT# will remain asserted until the processor exits the low power state and the processor junction temperature drops below the thermal trip point.

If automatic mode is disabled the processor will be operating out of specification. Whether the automatic or On-Demand modes are enabled or not, in the event of a catastrophic cooling failure, the processor will automatically shut down when the silicon has reached a temperature of approximately 125 °C. At this point the FSB signal THERMTRIP# will go active. THERMTRIP# activation is independent of processor activity and does not generate any bus cycles. When THERMTRIP# is asserted, the processor core voltage must be shut down within the time specified in Chapter 3.

This page intentionally left blank.

6 Debug Tools Specifications

Please refer to the *ITP700 Debug Port Design Guide* and the platform design guides for information regarding debug tools specifications.

6.1 Logic Analyzer Interface (LAI)

Intel is working with logic analyzer vendors to provide LAIs for use in debugging Intel Celeron M processor systems. The following information is general in nature. Specific information must be obtained from the logic analyzer vendor.

Due to the complexity of Intel Celeron M processor-based systems, the LAI is critical in providing the ability to probe and capture FSB signals. There are two sets of considerations to keep in mind when designing a Intel Celeron M processor-based system that can make use of an LAI: mechanical and electrical.

6.1.1 Mechanical Considerations

The LAI is installed between the processor socket and the Intel Celeron M processor. The LAI pins plug into the socket, while the Intel Celeron M processor pins plug into a socket on the LAI. Cabling that is part of the LAI egresses the system to allow an electrical connection between the Intel Celeron M processor and a logic analyzer. The maximum volume occupied by the LAI, known as the keepout volume, as well as the cable egress restrictions, should be obtained from the logic analyzer vendor. System designers must make sure that the keepout volume remains unobstructed inside the system.

6.1.2 Electrical Considerations

The LAI will also affect the electrical performance of the FSB; therefore, it is critical to obtain electrical load models from each of the logic analyzers to be able to run system level simulations to prove that their tool will work in the system. Contact the logic analyzer vendor for electrical specifications and load models for the LAI solution they provide.
