

# IH5216 ই 8-Channel Differential ই **Fault Protected CMOS Analog Multiplexer**

#### **GENERAL DESCRIPTION**

The IH5216 is a dielectrically isolated CMOS monolithic analog multiplexer, designed as a plug-in replacement for the HI547 and similar devices, but adding fault protection to the standard performance. A unique serial MOSFET switch ensures that an OFF channel will remain OFF when the input exceeds the supply rails by up to ±25V, even with the supply voltage at zero. Further, an ON channel will be limited to a throughput of about 1.5V less than the supply rails, thus affording protection to any following circuitry such as op amps, D/A converters, etc. Cross talk onto "good" channels is also prevented.

A binary 3-bit address code together with the ENable input allows selection of any channel pair or none at all. These 4 inputs are all TTL compatible for easy logic interface. The ENable input also facilitates MUX expansion and cascading.

#### ORDERING INFORMATION

Part Number	Temperature Range	Package
IH5216MJI	- 55°C to + 125°C	28 pin CERDIP

#### **FEATURES**

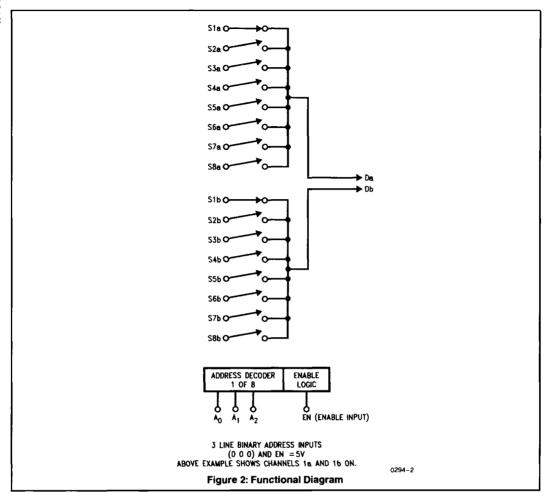

- . All Channels OFF When Power OFF, for Analog Signals Up to ±25V
- Power Supply Quiescent Current Less Than 1mA
- ± 13V Analog Signal Range
- No SCR Latchup
- Break-Before-Make Switching
- TTL and CMOS Compatible Strobe Control
- Pin Compatible With HI547
- Any Channel Turns OFF If Input Exceeds Supply Rails By Up to ±25V
- TTL and CMOS Compatible Binary Address and **ENable Inputs**

## IH5216

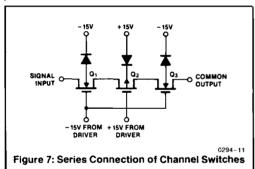

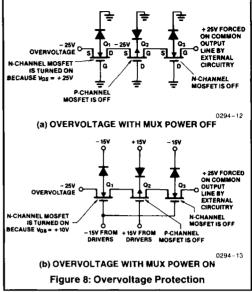

The IH5216, like all Harris' multiplexers, contains a set of CMOS switches that form the channels, and driver and decoder circuitry to control which channel turns ON, if any. In addition, the IH5216 contains an internal regulator which provides a fully TTL compatible ENable input that is identical in operation to the Address inputs. This does away with the special conditions that many multiplexer enable inputs require for proper logic swings. The identical circuit conditions of the ENable and Address lines also helps ensure the extension of break-before-make switching to wider multiplexer systems (see applications section)

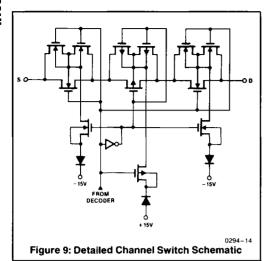

Another, and more important difference lies in the switching channel. Previous devices have used parallel n- and pchannel MOSFET switches. While this scheme yields reasonably good ON resistance characteristics and allows the switching of rail-to-rail input signals, it also has a number of drawbacks. The sources and drains of the switch transistors will conduct to the substrate if the input goes outside the supply rails, and even careful use of diodes cannot avoid channel-to-output and channel-to-channel coupling in cases of input overrange. The IH5216 uses a novel series arrangement of the p- and n-channel switches (Figure 7) combined with the dielectrically isolated process to eliminate these problems.

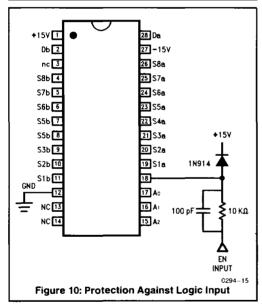

Within the normal analog signal range, the inherent variation of switch ON resistance will balance out almost as well as the customary parallel configuration, but as the analog signal approaches either supply rail, even for an ON channel, either the p- or the n-channel will become a source follower, disconnecting the channel (Figure 8). Thus protection is provided for any input or output channel against overvoltage, even in the absence of multiplexer supply voltages. This applies up to the breakdown voltage of the respective switches. Figure 9 shows a more detailed schematic of the channel switches, including the back-gate driver devices which ensure optimum channel ON resistances and breakdown voltage under the various conditions.

Under some circumstances, if the logic inputs are present but the multiplexer supplies are not, the circuit will use the logic inputs as a sort of phantom supply; this could result in an output up to that logic level. To prevent this from occurring, simply ensure that the ENable pin is LOW any time the multiplexer supply voltages are missing (Figure 10).

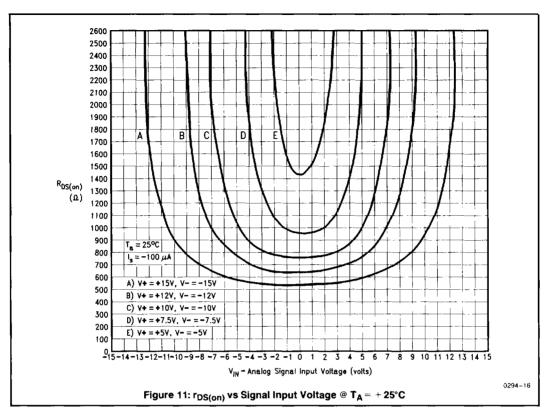

## MAXIMUM SIGNAL HANDLING CAPABILITY

The IH5216 is designed to handle signals in the  $\pm\,10V$  range, with a typical  $r_{DS(on)}$  of  $900\Omega;$  it can successfully handle signals up to  $\pm\,12V$ , however,  $r_{DS(on)}$  will increase to about 1.8k $\Omega$ . Beyond  $\pm\,12V$  the device approaches an open circuit, and thus  $\pm\,12V$  is about the practical limit, see Figure 11.

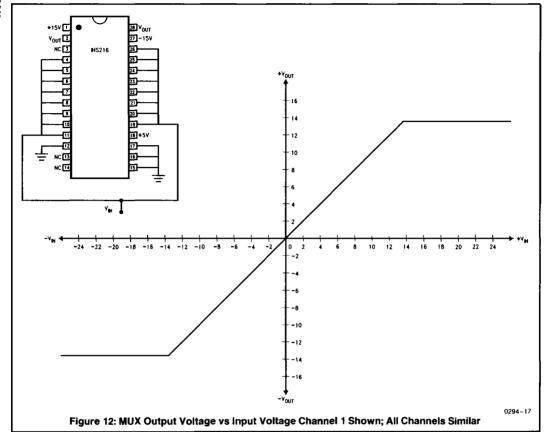

Figure 12 shows the input/output characteristics of an ON channel, illustrating the inherent limiting action of the series switch connection (see Detailed Description), while Figure 13 gives the ON resistance variation with temperature

## USING THE IH5216 WITH SUPPLIES OTHER THAN $\pm$ 15V

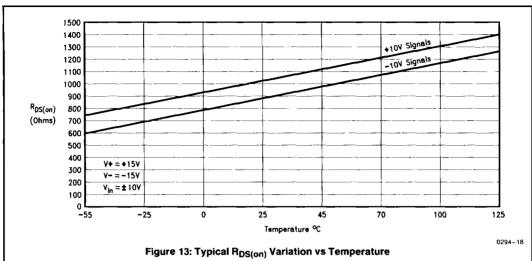

The IH5216 will operate successfully with supply voltages from  $\pm 5V$  to  $\pm 15V$ , however  $r_{DS(on)}$  increases as supply voltage decreases, as shown in Figure 11. Leakage currents, on the other hand, decrease with a lowering of supply voltage, and therefore the error term product of  $r_{DS(on)}$  and leakage current remains reasonably constant.  $r_{DS(on)}$  also decreases as signal levels decrease. For high system accuracy [acceptable levels of  $r_{DS(on)}$ ] the maximum input signal should be 3V less than the supply voltages. The logic thresholds remain TTL compatible.

## General note on expandability

Figures 14, 15, and 16 show how the IH5216 is expanded. Figure 14 shows a 2 of 32 multiplexer, using 2 IH5216s. Corresponding output points of each of the IH5216s are connected together, and the ENable input strobe is used as the A<sub>3</sub> input. Since each output (pins 2 and 28) corresponds

to an "ON" FET and an "OFF" FET, the overall system looks like 1 "ON" FET and 7 "OFF" FETs for each of the  $V_{out1}$  and  $V_{out2}$  outputs. Thus the output leakage will be 1  $I_{D(on)}$  plus 7  $I_{D(off)}$ s or about 0.45nA at room temperature. Throughput speed will be typically 0.6 $\mu$ s for  $t_{on}$  and 0.4 $\mu$ s for  $t_{off}$ , with throughput channel resistance in the 950 $\Omega$ 

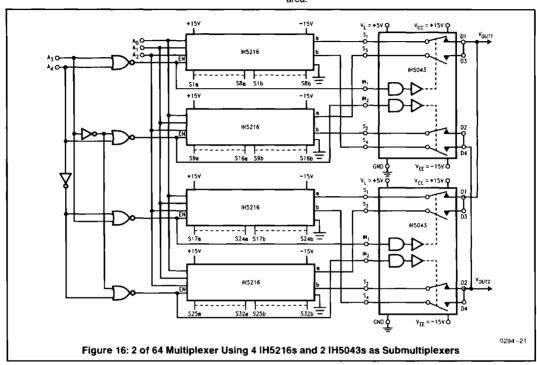

Figure 15 shows the 2 of 32 MUX, with a second tier of submultiplexing added to reduce leakage and output capacitance. The IH5043 has typical ON resistance of  $50\Omega$  (max. is 75Ω) so it only increases throughput channel resistance from the 900 ohms of Figure 14 to about 950 ohms for Figure 15. Throughput channel speed is a little slower by about 0.5 $\mu$ s for both ON and OFF time, and output leakage is about 0.2nA.

Figure 16 shows a 2 of 64 MUX using 2 tier MUXing (similar to Figure 15). The IH5043 is used for the second tier of MUXing. Each  $V_{\rm out}$  point will see 7 OFF channels and 1 ON channel at anytime, so that the typical leakages will be about 0.45nA. Throughput channel resistance will be in the 950 $\Omega$  area and throughput switching speeds about 1.3 $\mu$ s for ON time and 0.8 $\mu$ s for OFF time.

The IH5043 was chosen as the second tier of the MUX because it will switch the same AC signals as the 5216 (typically plus and minus 15V) and uses break before make switching. Also power supply quiescent currents are typically 1-2 $\mu$ A so that no excessive system power is generated. Note that the logic of the 5043 is such that it can be tied directly to the ENable input (as shown in the figures) with no extra logic being required.

## **Enable input strobing levels**

The ENable input acts as an enabling or disabling pin for the 5216 when used as a 2 out of 16 channel MUX, however when expanding the MUX to more than 16 channels, the EN pin acts as another address input. Figures 14 and 15 show the EN pin used as the  ${\sf A}_3$  input. TTL and the Enable input is CMOS compatible.
